<sup>4</sup> **Abstract**

<sup>5</sup> 1) DNA Barcoding has been remarkably successful in nearly all kingdoms of life and has allowed  
<sup>6</sup> for the rapid analysis of ecological assemblages. Successful DNA barcoding in the plant kingdom  
<sup>7</sup> has been more difficult than other kingdoms. Due to this understanding plants in ecological  
<sup>8</sup> contexts and understandings of their synecology in some instances may begin to lag behind other  
<sup>9</sup> kingdoms.

<sup>10</sup> 2) Here we utilize hyb-seq, museum studies, and species distribution modelling, to detect the plant  
<sup>11</sup> species present in pollen loads collected from Queen Bumble Bees.

<sup>12</sup> 3) By utilizing Species distribution modelling we allow for one to process hyb-seq data, create user  
<sup>13</sup> specified sequence databases which may use MORE ACCURATE alignment algorithms on personal  
<sup>14</sup> computers over realistic time periods.

<sup>15</sup> 4) We show that hyb-seq using the Angiosperms 353 probes, which are currently being used in the  
<sup>16</sup> largest ever plant systematic endeavor, offers significant promise to metagenomic approaches in  
<sup>17</sup> real world scenarios.

<sup>21</sup> \*Correspondence: reedbenkendorf2021@u.northwestern.edu

22 5) We conclude that these probes offer promise for the identification of plant tissue in both single  
23 sample, and metasample contexts.

24 **1 | INTRODUCTION**

25 The inability to reliably identify plants down to species can limit our understanding of ecosystem function  
26 and interactions (Bortolus (2008)). This is especially true for genera where species are defined based upon  
27 ecological and behavioral rather than morphological properties, and hence can serve as key habitat bioindi-  
28 cators (e.g. different species of Sagebrush- *Artemisia* L., Willows - *Salix* L., and Sedges - *Carex* L.) (Gage &  
29 Cooper (2013)). The lack of species level data can hinder our understanding of the breadth of habitat which  
30 some species occupy, and the interactions they have with other species. Current methods to ameliorate this  
31 situation include: ignoring these ecologically relevant levels of detail, revisiting plots as diagnostic mate-  
32 rial becomes temporally available, assistance from taxonomic specialists, or the use of barcoding or other  
33 molecular techniques.

34 The identification to species is often mired by lack of diagnostic characters (e.g. flowers, fruits, roots or  
35 combinations thereof), an increasing lack of taxonomic experts (Hebert *et al.* (2003)) and increasingly the  
36 description of cryptic species (Janzen *et al.* (2017), Oliver *et al.* (2009)). And revisiting field sites to identify  
37 material using morphological or chemical approaches, can be resource intensive and often does not work.

38 Recently barcoding (the identification of a sample from a single organism *e.g.* a piece of leaf), and metabar-  
39 coding (the identification of a sample containing a mix of organisms *e.g.* soil), have shown considerable  
40 promise in all Kingdoms of life (Ruppert *et al.* (2019)). With plants the identification of members of cer-  
41 tain clades using barcoding has been quite successful (Kress (2017)), whereas with other clades results have  
42 been elusive (Liu *et al.* (2014), Group *et al.* (2011), Coissac *et al.* (2012)), however metabarcoding incurs  
43 additional challenges to those which exist for the currently implemented barcodes (Li *et al.* (2015), Kress &  
44 Erickson (2007), Group *et al.* (2009), Coissac *et al.* (2012)). Particular challenges with barcodes include the  
45 utilization of high-copy number sequences are associated with their rates of divergence, gene tree conflict,  
46 and hybridization (Coissac *et al.* (2016), Fazekas *et al.* (2009)).

47 Currently the largest plant systematic endeavor ever undertaken, the Kew Plant and Fungal Tree of Life  
48 (PAFTOL), is approaching completion (Baker *et al.* (2021a)). This data set will contain hybridization  
49 capture (Hyb-Seq) data from at least one species representing each genus in the plant kingdom using the  
50 popular A353 probes (Baker *et al.* (2021a)), resulting in over 14,000 represented species. These publicly  
51 available data serve to provide a taxonomically comprehensive backbone for plant metabarcoding, and the

52 A353 probes are currently being used in many other plant phylogenetic issues increasing the sampling depth  
53 of many clades (Baker *et al.* (2021b)). Data from the 10kP project, which seeks to develop reference  
54 genomes from a phylogenetically diverse suite of plants will contribute many more records upon it's intended  
55 completion, now slated to be by 2030, similar projects which seek to sequence high amounts of genomes in  
56 regions e.g. the 'Darwin Tree of Life' are being undertaken which will contribute data applicable to enormous  
57 spatial domains (Cheng *et al.* (2018), Life Project Consortium *et al.* (2022), Lewin *et al.* (2022)). These  
58 data will promote the ability to apply metabarcoding to resolve a diversity of questions relevant to theoretical  
59 and applied ecology (Kress (2017)). However, the application of metabarcoding still face challenges relating  
60 to the enormity of the genomic data sets and the computational power required to process sequence data.  
61 Herein we have resolved major components of the problems of identifying plant material without diagnostic  
62 morphological character states using the Angiosperms353 (A353) Hyb-Seq probes (Johnson *et al.* (2019)),  
63 and custom species sequence databases derived via species distribution modelling, and temporal filtering.

64 To increase the quality of metabarcoding results in plants, we suggest reducing the number of possible  
65 plant species candidates by generating user selected sequence databases relevant to the the study region and  
66 its ecological characteristics. To achieve this goal, we first create a list of candidate species using digital  
67 collections gleaned from herbaria, survey work, and citizen science (e.g. iNaturalist), from a region exceeding  
68 the study area. To these candidate species, modelling approaches - such as logistic regression, may be used  
69 to identify taxa which warrant further exploration e.g. modelling to determine their possibility of presence  
70 in metabarcoding samples. We then use species distribution models to create potential distribution maps  
71 for the candidate species to limit the impact of spatial and taxonomic biases in the species list and account  
72 for spatial variations in niche availability throughout the study area. Species distribution models (SDM's)  
73 examine the ecological conditions associated with known occurrence of a species to identify where else in the  
74 study area might suitable habitats be found. This approach has the additional benefit of greatly reducing  
75 the size of a sequence database, which allows for the usage of genomic size data on personal computers.  
76 This can also significantly reduce processing time, particularly as as most next-generation sequence data is  
77 deposited as raw-sequence reads.

78 Considerable amounts of species interactions vary along time (CaraDonna *et al.* (2021)). For the tropics  
79 and subtropics, contrasts in the flowering periods of many plant species, can provide an additional filter for  
80 identifying material in many metagenomic samples (Janzen (1967), Newstrom *et al.* (1994)). In temperate  
81 regions, pollination interactions also vary temporally (CaraDonna *et al.* (2017)), however the overall shorter  
82 extent of the active growing season in these systems results in the presence of few to any natural breaks  
83 in these systems which reduces the utility of these to operate as filters in the post-processing of sequence

84 matches. Nonetheless, we work through a process which seems applicable to the tropics and subtropics to  
85 utilize the temporal dimension for classifying sequencing results.

86 To test these metagenomic and informatics approaches to determine whether the foraging record of Queen  
87 Bumble Bee's is consistent across direct observations and the pollen record, an incongruency in several floral  
88 visitation networks involving smaller bodied fauna (Barker & Arceo-Gomez (2021), Zhao *et al.* (2019),  
89 Alarcón (2010)). The assessment of the plant species compositions of pollen is a desired results, with several  
90 applications, and numerous complications (Poron *et al.* (2017), Bell *et al.* (2017), Sickel *et al.* (2015),  
91 Bell *et al.* (2019), Suchan *et al.* (2019), Johnson *et al.* (2021)). The two foraging phases of the Queen  
92 Bumble Bee life cycle is essential to 1) increase their weight before diapause, 2) increase their ovary weights  
93 while establishing their recently found nests, both of these time periods represent potential demographic  
94 bottlenecks in bumble bee populations (Sarro *et al.* (2022)). Bumblebees are one of the only groups of insects  
95 with unequivocal quantitative evidence for numerous populations declines, while simultaneously serving as  
96 the most effective pollinators in temperate montane ecosystems (Cameron & Sadd (2020), Goulson *et al.*  
97 (2008), Williams (1982), Colla *et al.* (2012), Bergman *et al.* (1996), Bingham & Orthner (1998)). Montane  
98 areas often represent the most diverse areas in the temperate and oftentimes offer the sole potential refugia  
99 for multiple dimensions of biodiversity under climate change, whilst simultaneously experiencing the greatest  
100 proportional changes in mean annual temperature (Brito-Morales *et al.* (2018), Pepin *et al.* (2022)). An  
101 immediate understanding of how to manage previously overlooked keystone insect species, such as bumble  
102 bees, is essential if the refugial potential of the temperate mountains are to be utilized while maintaining  
103 their current diversity (Loarie *et al.* (2009), Dobrowski & Parks (2016))

## 104 2 | METHODS

### 105 Study System & Field Work

106 Observations and sample collection was conducted at The Rocky Mountain Biological Laboratory (RMBL;  
107 38°57.5" N, 106°59.3" W (WGS 84), 2900 m.a.s.l.), Colorado, USA (APPENDIX 1 for site information). Pol-  
108 linator observations of *Bombus Latreille* spp. (Apidae Latreille) were conducted from June - August of 2015  
109 in six study sites characterized by high-montane/subalpine Parkland vegetation communities. Observations  
110 of *Bombus* foraging took place for one hour at each field site in three 100m transects, where all flowers were  
111 also counted and placed into abundance bins. Corbiculae loads were, non-lethally, collected once from all  
112 Queen individuals encountered.

113 **2.1 | Spatial Analyses**

114 **2.1.1 Candidate Species** We downloaded from the Botanical Information and Ecology Network ‘BIEN’  
115 (Maitner (2022)) all records adjacent to the field sites to develop an ecologically relevant list of vascular  
116 plant species, with expected biotic pollination, which may be present at the study area . We then generated  
117 Species Distribution Models (SDMs) to predict their distribution throughout the study area. These maps of  
118 potential distribution served as a reference to reduce the list of species to include in the genomic sequence  
119 databases.

120 In order to minimise the number of species for which SDM’s were to be generated, BIEN was queried at  
121 a distance of up to 100km from our study area and all plant species records were downloaded. In order  
122 to emulate the stochasticity of botanical collecting, this data set was bootstrap re-sampled 250 times, with  
123 90% of samples selected, to create a testing data set. The median of the logistic regression assessing the  
124 probability of occurrence of a species record as a function of distance from the study area was used as a  
125 threshold distance, under which, to include species as candidates for distribution modelling.

126 **2.1.2 Distribution Modelling** We used all occurrence records from BIEN ( $n = 23,919$ ) within a 50km  
127 border of the Omernik level 3 ecoregion, which includes the study area (*No. 21 “Southern Rockies”*) to  
128 construct the species distribution model (Omernik (1987)). These records were copied into two, initially  
129 identical, sets, one for generating machine learning models (ML; Random Forest, and Boosted Regression  
130 Tree’s), and the other for Generalised Linear (GLM) and Generalized Additive Models (GAM) (Barbet-  
131 Massin *et al.* (2012)). **Ensembled predictions have been shown to outperform their constituent**  
132 **models, on average, and to reduce the ecological signal to the analytical noise of individual runs**  
133 **(Araujo & New (2007)). No single method of producing SDMs has been shown to universally**  
134 **outperform others when faced with a large and diverse number of applications, in our case a**  
135 **great number of species with differing biologies and ecologies (Elith\* *et al.* (2006), Qiao *et al.***  
136 **(2015)). In the spirit of these findings, multiple families of models, which can be generated**  
137 **together as they have similar requirements regarding the number and ratios of Presence to**  
138 **Absence records were ensembled together (Barbet-Massin *et al.* (2012)).**

139 We then generated 4,029 absence points , locations where the focal taxon is anticipated missing, through a  
140 random stratification of 19% of the land cover in the area and included them in (BLM CITATION - need  
141 appropriate format for journal). To achieve a larger absence data set, we generated 1,000 pseudo-absence  
142 records for each taxon by randomly selecting coordinates located at least 10km away from an occurrence  
143 record. For ML models, these pseudo-absences were reduced so that the ratio of presence to absence records

<sup>144</sup> were balanced (Barbet-Massin *et al.* (2012)). To achieve this, we removed absence records inside of 10% of  
<sup>145</sup> the mean sample value of the presence records; the required number of absence records were then randomly  
<sup>146</sup> sampled.

<sup>147</sup> We used 26 environmental variables at 30m resolution to predict the potential distribution of each species,  
<sup>148</sup> six related to climate, five soil, four topographic, four related to cloud cover, with the remaining reflecting  
<sup>149</sup> assorted abiotic parameters (Wilson & Jetz (2016), Wang *et al.* (2016), Hengl *et al.* (2017), Robinson *et al.*  
<sup>150</sup> (2014)) (**APPENDIX 6**). **These publicly available data sets, were selected as they . . .** For linear  
<sup>151</sup> regression models these predictors underwent both *vifstep* (theta = 10, max observations = 12,500) and  
<sup>152</sup> *vifcor* (theta = 0.7, max observations = 12,500) to detect highly correlated variables, and collinear features  
<sup>153</sup> were removed leaving 16 variables (Naimi *et al.* (2014)).

<sup>154</sup> Modelling: Random Forest and Boosted Regression Trees, were sub sampled with 30% test and two replicates  
<sup>155</sup> each before weighted ensemble based on True Skill Statistics (tss) (Naimi & Araujo (2016)). Generalised  
<sup>156</sup> linear models (GLM) and Generalised additive models (GAM) with 30% sub sampling and three replicates  
<sup>157</sup> each were also ensembled using the tss (Naimi & Araujo (2016), @). TSS was chosen as the ensemble  
<sup>158</sup> criterion as it has been shown to work across a range of species occurrences prevalence (Allouche *et al.*  
<sup>159</sup> (2006)). The results of these models were extracted on a cell-by-cell basis to a polygon feature derived from  
<sup>160</sup> a minimum-spanning tree which encompasses the study sites, and species from either ensemble with greater  
<sup>161</sup> than 50% mean habitat suitability across all cells were considered present for further purposes (Prim (1957)).

<sup>162</sup> 535 species were modelled using Generalized Linear Models and Generalized Additive Models. 534 species  
<sup>163</sup> were modelled using Random Forest and Boosted Regression Trees. To evaluate the accuracy of the species  
<sup>164</sup> distribution models, additional presence records from GBIF (n = 61,789), and AIM (n = 12,730) were used as  
<sup>165</sup> test and training sets (n = 74,519) for logistic regression (Occdownload Gbif.Org (2021), Land Management  
<sup>166</sup> (2020)). Additional novel absence records were generated from the AIM data set to create a data set where  
<sup>167</sup> each species has balanced presence and absences. 11 or more paired presence and absence records were  
<sup>168</sup> required for this testing, resulting in 334 species being included in the logistic regression (Mdn = 110.0,  $\bar{x}$  =  
<sup>169</sup> 223.1, max = 1568 record pairs used) with a 70% test split (Kuhn (2022)).

## <sup>170</sup> 2.2 | Molecular Lab Work

<sup>171</sup> All lab work was carried out at The Daniel F. and Ada L. Rice Plant Conservation Science Center at the  
<sup>172</sup> Chicago Botanic Garden, Glencoe, Illinois, U.S.A.

173 **2.2.1 | Reference Plant Library Generation** Using five years of observational data on *Bombus* Queen  
174 Bee foraging at these studies sites, we identified the plant taxa most frequently visited by Queens across  
175 all years. We sequenced the 12 most commonly visited taxa twice using samples from one site within the  
176 Gunnison River Drainage and one individual from another population. In addition, for any of these 12 focal  
177 species which did not have a congener pair in this filtered sample, we included a congener - or a species from a  
178 closely related genus to serve as an outgroup. We also sequenced another 15 abundant taxa commonly visited  
179 by *Bombus* workers, based on the aforementioned data set (*APPENDIX 4*). Plant collections were identified  
180 via a variety, and typically a combination, of dichotomous keys and primary literature as required (Flora of  
181 North America Editorial Committee (1993+), Hitchcock & Cronquist (2018), Ackerfield (2015), Lesica *et al.*  
182 (2012), Cronquist *et al.* (1977+), Allred & Ivey (2012), *Jepson flora project* (2020), Mohlenbrock (2002)).

183 **2.2.2 | Plant Genomic DNA Extraction** Plant genomic DNA was isolated from ~ 1 cm<sup>2</sup> of leaf tissue  
184 from silica-gel dried or herbarium material using a modified cetyltrimethylammonium (CTAB) protocol  
185 (Doyle & Doyle (1987)) that included two chloroform washes. DNA was quantified using a Nanodrop 2000  
186 (Thermo Fisher Scientific, Waltham, Massachusetts, USA) and Qubit fluorometer (Thermo Fisher Scientific).

187 **2.2.3 | Pollen Genomic DNA Extraction** Pollen genomic DNA was extracted from corbiculae using a  
188 CTAB based protocol modified from Lahlamgiah et al. and Guertler et al. (2014, 2014). A SDS extraction  
189 buffer (350µL , 100mM Tris-HCl, 50 mM EDTA, 50 mM NaCl, 10% SDS v/v., pH 7.5) was added followed by  
190 vortexing to allow dissolution of corbiculae. Pollen grains were then macerated with Kontes Pellet Pestles,  
191 and the tip of these washed with 130 µL of the SDS extraction buffer, samples were then incubated for  
192 1 hour at 30°C. This was followed by the addition of 10% CTAB solution (450ul, of 20 mM Tris-Cl pH.  
193 8.0, 1.4 M NaCl, 10 mM EDTA pH 7.5, 10% CTAB, 5% PVP, ~85% Deionized water) and RNase (10  
194 uL of 10 mg/mL) and samples were incubated for 40 minutes at 37°C, on heat block (Multi-Blok, Thermo  
195 Fisher Scientific, Waltham Massachusetts) set to 40°C. After 20 minutes incubation, Proteinase K (15 µL of  
196 20mg/ml) and DTT (12.5 µL of 1M in water) were added, and the samples were further incubated at 60°C  
197 for 1 hour. Samples were then incubated overnight at 40°C. 500 µL of Phenol-Chloroform-Isoamyl alcohol  
198 (25:24:1) were added, vortexed, and centrifuged at 10,000 rpm for 10 minutes and the aqueous phase was  
199 pipetted to a 1.5 ml centrifuge tube.

200 To precipitate the DNA, chilled Isopropyl alcohol & 3 mM Sodium acetate (5:1) equivalent to 2/3 of the  
201 volume of sample were added, with 1 hour of chilling at -20°C, followed by 10 minutes of centrifuging at  
202 13,000 rpm. The supernatant was pipetted to a new 1.5 ml centrifuge tube, and 70% EtOH (400 µL) were

203 added before chilling at -20°C for 20 minutes followed by centrifugation at 13,000 rpm for 10 minutes. Both  
204 tubes were then washed with 75% EtOH (400 µL), inverted, centrifuged at 13,000 rpm for 4 minutes, and  
205 the solution discarded, then washed with 95% EtOH (400 µL) , inverted, centrifuged at 13,000 rpm for 4  
206 minutes, and the solution discarded. Pellets were dried at room temperature overnight before resuspension  
207 in Nuclease free H<sub>2</sub>O. Extractions were assessed using a Nanodrop 2000 (Thermo Fisher Scientific) and  
208 Qubit fluorometer (Thermo Fisher Scientific). DNA extracts were then cleaned using 2:1 v./v. Sera-Mag  
209 beads (Cytiva, Little Chalfont, UK) to solute following the manufacturer's protocol, eluted in 0.5x TE, and  
210 the eluent allowed to reduce by half volume in ambient conditions. DNA was quantified using a Qubit  
211 fluorometer.

212 **2.2.4 | Fragmentation, Library Preparation & Target Enrichment** Library preparation was per-  
213 formed using the NEBNext Ultra II FS-DNA Library Prep Kit for Illumina (New England BioLabs, Ipswich,  
214 Massachusetts, USA) using slightly modified manufacturers recommendation. Fragmentation was performed  
215 at ½ volume of reagents and ¼ enzyme mix for 40 minutes at 37°C, with an input of 500 ng cleaned DNA.  
216 Adapter Ligation and PCR enrichment were performed with ½ volumes, while cleanup of products was  
217 performed with ½ volume of SPRI beads (Beckman Coulter, Indianapolis, Indiana, USA) and recommended  
218 volumes of 80% v./v. ethanol washes. The exception was the herbarium specimens which were not frag-  
219 mented and only end repaired, with similar library preparation of all samples. Products were analysed on  
220 4% agarose gels, and a Qubit fluorometer. Libraries were pooled and enriched with the Angiosperms 353  
221 probe kit V.4 (Arbor Biosciences myBaits Target Sequence Capture Kit) by following the manufacturer's  
222 protocol and Brewer et al. 2019. Sequencing was performed using an Illumina mi-Seq with 150-bp end reads,  
223 (NUSeq Core, Chicago, Illinois).

224 **2.2.5 | Computational Processes and Analyses.**

225 **2.2.5.1 | Reference Library Data Processing** Sequences were processed using Trimmomatic, which  
226 removed sequence adapters, clipped the first 3 bp, discarding reads less than 36 bp, and removing reads  
227 if their average PHRED score dropped beneath 20 over a window of 5 bp (Bolger & Giorgi (2014), Tange  
228 (2021)). Contigs were generated using HybPiper using target files created by M353 (Johnson *et al.* (2016),  
229 McLay *et al.* (2021)).

230 **2.2.5.2 | Sequence Identification** A custom Kraken2 database was created by downloading represen-  
231 tative species of each genus indicated as being present in the study area by the spatial analyses from the

232 Sequence Read Archive (SRA) NCBI (Wood *et al.* (2019)). These sequences were processed in the same  
233 manner as our novel sequences . The Kraken2 database was built using default parameters. Kraken2 was  
234 run on sequences using default parameters (*APPENDIX 5*). Following Kraken2, Bracken was used to clas-  
235 sify sequences to terminal taxa (Lu *et al.* (2017)). Results from both Kraken2 and Bracken, results were  
236 reclassified manually to identify terminal taxa. For example, when only a single species of a genus was known  
237 in the study area, but our database used a representative of another taxon in the genus, this species was  
238 coded as the result. The re-coding of sequences from another representative species for the genus to the sole  
239 RMBL representative allowed the identification of XX & % more species.

240 **2.2.5.3 | Identification of Sequence Matching Loci** A local NCBI database was built using the same  
241 processed novel and downloaded sequences as the previous databases (Camacho *et al.* (2009)).

#### 242 **2.2.5.4 | Morphological Pollen identification**

243 To develop a reference library of pollen grains which may be present in corbiculae loads, an image reference  
244 collection of fuchsin-jelly stained (Beattie (1971)) slides was assembled from slides previously prepared by the  
245 authors (n = 21), and other researchers (n = 38) (Brosi & Briggs (2013)). Using five years of observational  
246 data on *Bombus* Queen Bee foraging at these studies sites (Ogilvie unpublished), as well as the Vascular  
247 Plant Checklist (Frase & Buck (2007)), an additional 62 voucher slides for species were prepared and imaged  
248 at 400x (Leica DMLB, Leica MC170 HD Camera, Leica Application Suite V. 4.13.0) from non accessioned  
249 herbarium collections to supplement the number of species and clades covered (Appendix 3).

250 We used Divisive Hierarchical Clustering techniques to determine which plant taxa were distinguishable via  
251 light microscopy, and to develop a dichotomous key to pollen morphotypes. Ten readily discernible categorical  
252 traits were collected from each specimen in the image collection. These traits were transformed using Gower  
253 distances, and clustered using Divisive Hierarchical clustering techniques (Maechler *et al.* (2022)). Using  
254 the cluster dendrogram, elbow plot, and heatmaps (Hennig (2020)), of these results morphological groups  
255 of pollen which could not be resolved via microscopy were delineated, and a dichotomous key was prepared  
256 (*APPENDIX NO.*). This key was then used to identify the pollen grains sampled from corbiculae loads to  
257 morphotypes in a consistent manner. To prepare the pollen slides from corbiculae, all corbiculae loads were  
258 broken apart and rolled using dissection needlepoints to increase heterogeneity of samples. *Cerca* 0.5mm<sup>2</sup>  
259 of pollen was placed onto a ~4mm<sup>2</sup> fuchsin jelly cube (Beattie (1971)) atop a graticulated microscope  
260 slide, with 20 transects and 20 rows (400 quadrants) (EMS, Hartfield, PA). The jelly was melted, with  
261 stirring, until pollen grains were homogeneously spread across the microscope slide. Slides were sealed with

262 Canada Balsam (Rublev Colours, Willits, CA) followed by sealing with nail polish; all samples are noted in  
263 *APPENDIX 3*. To identify the pollen present in corbiculae loads, light microscopy at 400x (Zeiss Axioscope  
264 A1) was used. In initial sampling in three transects, each pollen grain was identified to morphotype and  
265 counted; an additional two transects were scanned for morphotypes unique to that slide, if either transect  
266 contained an unique morphotype than all grains in that transect were also identified and counted. Subsequent  
267 to the first round osf sampling, non-parametric species richness rarefaction curves (Oksanen *et al.* (2022)),  
268 and non-parametric species diversity rarefaction curves were used to assess the completeness of sampling  
269 (Chao *et al.* (2014), Hsieh *et al.* (2020)). Slides not approaching the asymptote of the rarefaction curve  
270 were then re-sampled, and analysed iteratively for up to a total of seven transects *APPENDIX 2*.

271 **2.3 | Temporal Analyses**

272 To estimate the duration of dates in which plant species were flowering weibull estimates of several pheno-  
273 logical parameters all spatially modelled taxa were developed (Belitz *et al.* (2020), Pearse *et al.* (2017)).  
274 Only BIEN records which occurred in the Omernik Level 4 Ecoregions within 15km of the study area ( $n = 5$   
275 Level 4 Ecoregions, or conditionally 6 if enough records not be found in the nearest 5), and which were from  
276 herbarium records were included. To remove temporally irrelevant herbarium records, i.e. material collected  
277 during times which flowering is impossible at the study area due to snow cover, we used the SnowUS data  
278 set (Iler *et al.* (2021), Tran *et al.* (2019)) from 2000-2017 was analyzed for the first three days of contiguous  
279 snow absence, and the first three days of contiguous snow cover in Fall. Herbarium records after the 3rd  
280 quantile for melt, and the 1st quantile for snow cover of these metrics were removed. Species with  $> 10$   
281 records had their weibull distributions generated for the date when 10% of individuals had begun flowering,  
282 when 50% were flowering, and when 90% of individuals had flowered.

283 **2.4 | Floral Observations**

284 **3 | RESULTS**

285 **3.1 | Spatial Analyses**

286 [Table 1 about here.]

287 [Table 2 about here.]

288 The median (25.009 km) of the logistic regression assessing the probability of occurrence of a species record as  
289 a function of distance from the study area was used as a threshold distance to include species for distribution  
290 modelling. A 2-sample test for equality of proportions with continuity correction (X-squared = 13.254, df  
291 = 1, p-value = 0.000136, 95% CI 0.04-1.00) was used to test whether more of the records located in the  
292 broad ecological sites present at the field station, between the distance of the median (25.009 km) to the  
293 third quantile (ca 43.830 km) of the regression distance, where true presences at the field station. Including  
294 these records would have resulted in modelling an additional 222 species distributions of which 30 are true  
295 presences these taxa were not modelled.

296 Across the entire spatial domain of modelling all ensembled models (n = 968) had an accuracy of 0.84 (95%  
297 CI 0.8356 - 0.8443), kappa 0.68, p-value < 0.001, sensitivity = 0.80, specificity = 0.87, AUC = 0.92.

298 At the field site, of the 554 vascular plants with biotic pollination syndromes, the 493 ML ensembles accu-  
299 rately predicted the presence of 362 (65.3%), incorrectly predicted the presence of 64 (11.6%), incorrectly  
300 predicted 34 true presences (6.1%) as being absent, and correctly predicted the true absence of 33 (6.0%).  
301 The balanced accuracy of the ensembled models is 0.627 (Sensitivity = 0.340, Specificity 0.914). Of the 554  
302 vascular plants with biotic pollination syndromes, the 475 LM ensembles accurately predicted the presence  
303 of 286 (51.6%), incorrectly predicted the presence of 41 (14.3%), incorrectly predicted 93 true presences  
304 (16.8%) as being absent, and correctly predicted the true absence of 55 (9.9%). The balanced accuracy of  
305 the ensembled models is 0.664 (Sensitivity = 0.573, Specificity 0.754). Of the 554 vascular plants with biotic  
306 pollination syndromes in the flora 13 (2.3%) were in the Orchid family and 41 (7.4%) are non-natives, both  
307 of which are restricted from the database, and can only reduce the number of true predicted presences by  
308 roughly 10%.

309 At the six study plots, of the 117 plant species identified to the species level across the spatial extents of all  
310 plots and duration of queen bee activity, the ML ensembles predicted the presence of 105 (89.7%) of them,  
311 and LM ensembles 102 (87.2%). Of the missing species two (1.7%) are Orchids, six (5.1%) are non-native,  
312 and one (0.85%) is of contested taxonomic standing, all of which (7.65%) are restricted from the initial query  
313 database.

### 314 3.2 | Microscopic Pollen identification

315 Using the fuchsin jelly preparation and light microscopic analyses of grains and scoring of 10 character  
316 states resulted in the establishment of 28 morphotypes which grains could be classified into. APPENDIX  
317 7. 60 samples were counted and based on rarefaction **had over % of expected morphotypes found**

318 (morphotype richness,  $\bar{x} = 4.5$ , Mdn = 4, min = 1, max = 9), all samples had expected morphotype diversity  
319 reach the asymptote APPENDIX 8. The number of counted pollen grains in each sample range from (MIN  
320 - 16,293,  $\bar{x} = 2788.685$ , Mdn = 1453).

321 [Figure 1 about here.]

### 322 3.3 | Metabarcoding Pollen identification

323 54 corbiculae loads had DNA extracted and underwent various steps towards hyb-seq, in the end a total of  
324 44 corbiculae samples were sequenced, 7,752,353 reads were recovered from sequencing. The number of reads  
325 per sequence varied widely (range = 76 - 508,795,  $\bar{x} = 176,189.8$ , Mdn = 138,395). Of the possible 353 loci,  
326 the number which were recovered from each sample, and informative to BLAST were range = 24 - 353,  $\bar{x} =$   
327 305.5, Mdn = 331. The number of reads per loci from across all samples had a range of 178 - 506,653,  $\bar{x} =$   
328 20,688, Mdn = 12,616.

#### 329 APPENDIX X Reads Per Loci.

330 After trimming 7,865,680 sequences remained. 10,682,538 reads were matched using Kraken, of the reads  
331 classified by Kraken 10,160,768 reads were matched using Bracken, of the reads classified by Kraken 7,302,876  
332 reads were matched using BLAST.

333 Based upon subjective review of the three classifiers APPENDIX X MOLECULAR NETWORKS -  
334 3 DIFFERENT ONES, BLAST was chosen as the classification method which yielded the most probable  
335 results, and it's values were used for all subsequent analyses.

336 To determine at which level species in pollen loads could be detected the results of light microscopy were  
337 compared to the molecular results. The pollen samples contained three morphotypes which could readily  
338 be identified via microscopy. Two of these mapped to the clades (Boraginaceae & Heliantheae Alliance),  
339 and one to a Asteraceae less Heliantheae. Boraginaceae grains were detected in 85.7% of samples where the  
340 proportion of target grains were between 0.01-1 ( $n = 14$  Mdn = 0.572). Asteraceae type 1, non-helianthoids,  
341 were detected in 50% of samples where the proportion of target grains were between 0.001-0.01 ( $n = 6$  Mdn  
342 = 0.002) Asteraceae type 2, Helianthoids, were detected in 62.5% of samples where the proportion of target  
343 grains were between 0.001-0.01 ( $n = 8$  Mdn = 0.003). Both morphotypes of Asteraceae pollen were detected  
344 in 100% of samples where the proportion of target grains were between 0.01-1 ( $n = 3$  Mdn = 0.011).

345 **3.4 | Temporal Analyses**

346 The first date of modeled snow melt in the Gothic area ( $n = 17$ ,  $\bar{x} = 137.9$ , Mdn = 135, 3rd quantile = 151),  
347 and the first date of a consistent winter snow base ( $n = 17$ ,  $\bar{x} = 299.9$ , Mdn = 300, 1st quantile = 291) from  
348 2000-2017, were used as delimiters for the inclusions of herbarium records in modelling. Of the **500** species  
349 predicted likely present in the area via logistic regression, 332 species (64.4%) with more than 10 records in the  
350 focal level 4 ecoregions ( $\bar{x} = 35.01657$ , Mdn = 35, max = 96) had weibull estimates calculated, an additional  
351 56 species (11.2%) with enough contributing records from the “Sedimentary Mid-Elevation Forests”, a large  
352 ecoregion in general just beneath the elevation bands occupied by the five ecoregions around the study area  
353 had weibull estimates also calculated ( $\bar{x} = 13.86885$ , Mdn = 13, max = 24).

354 Only 58 of these 388 species ( $n = 34.56897$ , Mdn = 31) were able to be compared to plot based observational  
355 data from the long term (1974–2012) data set. Of these species relatively high accord was observed between  
356 the long-term ground truthed data set, and the modelled species. There was very strong evidence that the  
357 weibull estimates were positively associated with the observed onset ( $r^2 = 0.72$ ,  $p < 0.0001$ ,  $\tau = 0.61$ )  
358 and peak ( $r^2 = 0.70$ ,  $p < 0.0001$ ,  $\tau = 0.65$ ) of flowering, and that the number of herbarium samples had  
359 a moderate effect on the estimates ( $p = 0.004$  and  $p = 0.034$  respectively). There was very strong evidence  
360 that the weibull estimates had a positive association with the observed cessation of flowering ( $r^2 = 0.4339$ ,  $p$   
361  $< 0.0001$ ,  $\tau = 0.489$ ), however there was no evidence that sample size had an effect ( $p = 0.349$ ). There was  
362 moderate evidence that the weibull estimates, with an effect of sample size, had a weak positive association  
363 with the observed duration of flowering ( $p = 0.0401$ ,  $r^2 = 0.07$ ,  $\tau = 0.17$ ).

364 [Figure 2 about here.]

365 **3.5 | Floral Observations**

366 The six sites were surveyed for a total of 52 hours from May 27-July 27. A total of 723 queen-pollen foraging  
367 interactions were observed (range per bee species by week range = 1 - 18,  $\bar{x} = 3.46$ , Mdn = 2), with a  
368 range of total observed interactions per bee species across this time period (min = 1,  $\bar{x} = 59.08$ , Mdn = 19,  
369 max = 184). Plants varied widely in the number of interactions which they partook in with each species  
370 of bee (range per plant species by week min = 1 - 20,  $\bar{x} = 3.51$ , Mdn = 2), with a range of total observed  
371 interactions per plant species over this time period (min = 1,  $\bar{x} = 20.26$ , Mdn = 4, max = 141). The number  
372 of plant species which bees were observed interacting with varied more narrowly (range = 1 - 18,  $\bar{x} = 8$ ,  
373 Mdn = 6).

<sup>374</sup> A total of 66 corbiculae loads were collected from Bees, 64 of them from Queens.

<sup>375</sup> [Figure 3 about here.]

### <sup>376</sup> 3.6 | Integrated Observational, Molecular, and Palynological Network

## <sup>377</sup> 4 | DISCUSSION

<sup>378</sup> **overall stuff and things** We have demonstrated how Angiosperms533 hyb-seq probes may be used for  
<sup>379</sup> plant barcoding in a metagenomic context. This was exemplified in an ecologically realistic situation, cen-  
<sup>380</sup> tered both in a context which serves as an immediate framework for land management studies, and which  
<sup>381</sup> produced fundamental natural history information. These data sets included closely related taxa in notori-  
<sup>382</sup> ously taxonomically difficult clades (e.g. *Mertensia*, *Lupinus*). We utilized spatial and temporal approaches  
<sup>383</sup> for creating custom sequence databases which are readily applicable to any lab group with the capacity  
<sup>384</sup> to perform next-generation sequencing across the entirety of multiple continents. In conjunction with well  
<sup>385</sup> designed and implemented field based data collection we show how these methods may be widely used to  
<sup>386</sup> test a variety of hypotheses related to ecological interactions.

<sup>387</sup> *Complications* We likely had issues detecting pollen from several genera of plants, bsaed upon these and  
<sup>388</sup> other obesrvationla studies most likely Vicia-Lathyrus and Frasera (CITE), probably due to low quality  
<sup>389</sup> sequencing of whole plant material... (REED SHOULD HUNT FOR LOCI RETURNS FROM BLAST  
<sup>390</sup> LIKE HE DID POLLEN)

<sup>391</sup> These results show that the overall results between **Bumble Bee ecology** observational and barcoding are  
<sup>392</sup> largely congruent. But that ... Future analyses of the long term data set...

<sup>393</sup> **Spatial ... & Timing** (filters!) We have concerns regarding the number of persons training to become and  
<sup>394</sup> practice botany, and grave concerns regarding the funding mechanisms for floristic and field based botanical  
<sup>395</sup> research and for centralized authorities to produce consensus opinions on alpha taxonomy (Prather *et al.*  
<sup>396</sup> (2004b), Kramer & Havens (2015), Prather *et al.* (2004a), Crisci *et al.* (2020), Manzano (2021), Stroud  
<sup>397</sup> *et al.* (2022)). To reduce the effects of a low population density of botanists on the maintenance of and  
<sup>398</sup> production of flora's and to foster metagenomics across landscapes without field stations we utilized Species  
<sup>399</sup> Distribution Modelling to generate predictive species lists. In this proof of concept example we performed  
<sup>400</sup> several iterations of modelling runs, and several approaches (i.e. the ‘linear models’, and the ‘machine  
<sup>401</sup> learning’), which took notable amounts of compute power. We suspect the possible deleterious nature of

402 this endeavor may be reduced by: 1) more field surveying by crews will reduce the need to generate as many  
403 species 2) fewer runs of models, 3) only running machine learning models which do not require an explicitly  
404 process to reduce spatial autocorrelation. However, given the time required to perform all aspects of a study,  
405 even our amount of computation was negligible. Further, we are very optimistic about the possibility for  
406 persons to perform these tasks, as mentioned we utilized roughly only one quarter of the records which  
407 were digitally available for presence, and we suspect others will have enough records to perform this process  
408 nearly anywhere else in the temperate. Tandem to the lack of continued expertise required to generate  
409 and maintain species lists, is the expertise required to continue tracking when major phenological events  
410 occur in many plant species at relatively fine scales or under novel climates. Knowledge of these events is  
411 currently limited to general time periods of only a handful of phenological events and groups of organisms  
412 (e.g. flowering initiation, or trees) (Prather *et al.* (2004a), Li *et al.* (2016)). While many programs and  
413 initiatives exist to collect phenological information on subsets of easily identifiable charismatic species to  
414 detect major trends in phenology, by design these capture only a subset of the extent diversity (Betancourt  
415 *et al.* (2005), Havens *et al.* (2007)). In many instances it appears that while landscapes respond similarly  
416 to environmental variables which predict phenological responses, that individual species vary widely in their  
417 responses to similar environmental cues, or respond to different cues (Augspurger & Zaya (2020), Xie *et al.*  
418 (2015), Xie *et al.* (2018), CaraDonna *et al.* (2014)). As can be seen here, predictions of when a single, major  
419 phenological event occurs is already data limited, with sample size having an effect on the subset of species  
420 which we could even generate weibull estimates for.

421 **Molecular . . .** The nearly complete Plant and Fungal Tree of Life (PAFTOL) will provide a comprehensive  
422 phylogenetic backbone of the entire plant kingdom, and the inclusion of A353 probes with lineage specific  
423 probe sets is common in producing massive genetic datasets (Baker *et al.* (2021b)). We predict that the  
424 A353 probes which it is utilizing to work nearly immediately for DNA barcoding of whole plant material, and  
425 that more elaborate validation studies in controlled metabarcoding settings, utilizing existing experimental  
426 designs, will have favorable results (Bell *et al.* (2017), Bell *et al.* (2019)). In particular the harvesting of  
427 loci with more variation in certain lineages, and or with more variable flanking regions, will prove promising  
428 for identifying closely related plant material (CITE). We suspect that conserved reaches of genes resulted in  
429 the high amounts of reads in somewhat obscure species. Given that the A353 loci are nuclear, single copy,  
430 and a variety are present the possibility of identifying target loci for quantitative purposes is high, without  
431 continual PCR enrichment is possible. Recent evidence indicates that the potential for identifying nearly  
432 cryptic taxa and even infra-specific inference, of either whole plant material, and perhaps in metagenomic  
433 context are possible (Ottenlips *et al.* (2021), Wenzell *et al.* (2021), Loke et al. in prep, Slimp *et al.* (2021),

<sup>434</sup> Beck *et al.* (2021)).

## <sup>435</sup> 4 | CONCLUSION

<sup>436</sup> We believe that the combination of spatial and temporal models, united and guided by localized natural  
<sup>437</sup> history knowledge, provides the essential components of a bayesian framework for approaching the coarse  
<sup>438</sup> elucidation of ecological interactions using DNA Barcoding. Herein we crudely utilized this thinking via  
<sup>439</sup> binary outcomes, should a species predicted be predicted present or not? Is it unequivocally flowering  
<sup>440</sup> or not? Myriad data show biological systems and ecological interactions have more variance than can be  
<sup>441</sup> reasonably discretely parsed. We expect that within a bayesian framework studies of pollinator behavior  
<sup>442</sup> may be enacted via this approach at a landscape level, e.g. the scale of an entire drainage basin such as the  
<sup>443</sup> Gunnison which is quickly becoming one of the worlds few model ecosystems. We hope that the promise of  
<sup>444</sup> A353 probes as tools for metabarcoding play a role in these endeavors.

<sup>445</sup> **AUTHOR CONTRIBUTIONS:** R.C.B conducted botanical collections, conducted all molecular lab  
<sup>446</sup> work, lead all analyses, and writing. J.E.O conceived, designed, and conducted all ecological fieldwork,  
<sup>447</sup> assisted with analyses, and writing. E.J.W. prepared, imaged, and collected trait data on pollen reference  
<sup>448</sup> slides, and assisted with analysis of trait data and writing a dichotomous key. S.T. assisted with spatial  
<sup>449</sup> analyses and writing. P.J.C assisted with ecological analyses and writing. J.B.F. conceived, and designed all  
<sup>450</sup> lab work, analyses, and integration of approaches, assisted with writing, and secured funding for molecular  
<sup>451</sup> work.

<sup>452</sup> **ACKNOWLEDGMENTS:** Nyree Zerega for assistance obtaining herbaria loans and accessioning our  
<sup>453</sup> collections at CHIC. Pat Herendeen for assistance with virtually all aspects of preparing pollen vouchers  
<sup>454</sup> and the identification process. Ian Breckheimer for sharing the SDM predictor variables. Hilary Noble, Zoe  
<sup>455</sup> Diaz-Martinez, Angela McDonnell, & Elena Loke for assistance with genomic library preparation. We thank  
<sup>456</sup> the curators at the following herbaria for supplying tissue: Ben Legler at Stillinger (ID), Charles (Rick)  
<sup>457</sup> Williams at Ray J. Davis (IDS), (B)Ernie Nelson at Rocky Mountain (RM); and the collectors: D. Knoke,  
<sup>458</sup> L. Brummer, J. Boyd, C. Davidson, I. Gilman, M. Kirkpatrick, S. McCauley, J. Smith, K. Taylor, & C.  
<sup>459</sup> Williams. David Giblin & for sharing relevant sections of an advanced draft of FNA V. 15. The Bureau of  
<sup>460</sup> Land Management is thanked as many plant specimens were collected by R.C.B as a partner or contractor  
<sup>461</sup> to the agency, Sarah Burnett and Lauren Price are thanked for sharing AIM data. Sanda and NEB are  
<sup>462</sup> gratefully acknowledged for technical support and generously sharing samples. T.C.H. Cole for sharing the  
<sup>463</sup> Angiosperm Phylogeny 4 colour palette.

\* All Localities are in the United States of America

† Accession refers to whole-plant vouchers, all specimens are deposited at CHIC.

‡ Type Refers to whether both a physical and digital copy exist; 'Image' denotes only digital

§ Date refers to the Date of preparation.

- 1a: Pollen shed in clumps (tetrads/polyads); grains generally triangular, with an annulus subtending the porate apertures (go 34)
- 1b: Pollen generally dispersed as single units (monads); grains seldom if ever with annulus.
- 2a: Apertures porate, always lacking colpi
- 3a: grain outline from equatorial view circular
- 4a: Pores distributed along the equator.
- 5a: Pores > 5 (stephanoporate)
- 6a: Ornamentation homobrochate (~ *MENTZELIA*)
- 6b: Ornamentation otherwise (~ *POLYGALA*)
- 5b: Pores < 5 (*CURRENTLY OPEN*)
- 4b: Pores +/- distributed across grain (pantoporate)
- 7a: Ornamentation with striate ornamentation (~ *POLEMONIUM*)
- 7b: Ornamentation otherwise
- 8a: Ornamentation, slightly irregular - without regularly repeating features (scabrate) (~ *STELLARIA*)
- 8b: Ornamentation forming regularly repeating (reticulate) cells of varying shapes.
- 9a: spacing between the grid cells large (lophate), the walls of the cells with another set of projecting ornamentation (~ *OPUNTIA*)
- 9b: spacing between cells small, the wall of the cells without projecting features.
- 10a: Pores extending beyond the reticulate grids (~ *ARENARIA*)
- 10b: Pores extending beyond the reticulate grids (~ *PHLOX*)
- 3b: Outline from equatorial view otherwise (usually slightly triangular)
- 11a: Outline elliptic (*CURRENTLY EMPTY*)
- 11b: Outline not elliptic, grains often with acute, if rounded, angles along sides (e.g., triangular, polygonal) (*EMPTY*)
- 2b: Apertures with colpi, occasionally also with pores in addition (coporate)
- 12a: Grains with bristles tapering to points (echinate), and tri-colporate.
- 13a: Grains uniformly echinate, less the apertures. (Asteraceae 1)
- 13b: Grains with echinate bristles on ridges of lophae (Asteraceae 2)
- 12b: Grains without echinate ornamentation - this lead includes projections with ornamentation with round tips.
- 14a: Grains with either less than 3 apertures, or with two distinct ornamentation types (generally  $\frac{1}{2}$  psilate,  $\frac{1}{2}$  reticulate).
- 15a. Grains apparently lacking any apertures. (~ *IRIS*)
- 15b. Grains aperturate
- 16a. Ornamentation on one face of grain psilate, the other homobrochate (~ *ZIGADENUS + ANTICLEA*)
- 16b. Ornamentation psilate across both faces of grain (~*ERYTHONIUM*)
- 14b. Grains with either 3 or more apertures, or with an elongated spiral like aperture
- 17a. Grain with spiral like colpi
- 18a. Spiral with deep well-defined furrows (~ *ERYTHRANTHE GUTTATA*, syn. obsolete. *MIMULUS*)
- 18b. Spirals without well-defined grooves, ornamentation evidently perforate (~ *RANUNCULUS ALISMIFOLIUS*)
- 17b. Grains with colpi these not forming irregular spiral motifs.
- 19a. Grains elliptic, essentially perfectly cylindrical along longest axis, except for minor inundations along equatorial region. Apertures, of two types (heteroaperturate). (~ *BORAGINACEAE*)
- 19b Grains shaped similar or not, but never heteroaperturate.
- 20a. From a polar view, grains notably polygonal (hexagonal), also evident when seldom seen from a equatorial view. (~ *PHACELIA*/ maybe *Hydrophyllaceae*, *Hydrophyllum* not sampled)
- 20b. From a polar view, grains not with 6 convex apices

- 21a. Grains elliptic, with a short colporate aperture on each psilate face, the edges of each face and the apices with a distinct (homobrochate) textured ornamentation. (~ POLYGONUM)
- 21b. Grains otherwise, not featuring a mix of ornamentations independent of the apertures.
- 22a. Ornamentation perforate, the three colpi very short, their longest axis parallel to the equator rather than perpendicular. These colpi often times almost appearing to be slightly raised on an annulus like feature (~ LONICERA)
- 22b. Grains not as described in all aspects of the above.
- 23a. Apertures colporate
- 24a. Outline of grain in equatorial view circular, ornamentation smooth. (~MORPHOTYPE A).
- 24b. Grains otherwise
  - 25a Grains distinctly triangular from polar view (go 26)
  - 25b Grains elliptic (go 27)
    - 26a Grains very large, clearly strongly triangular in cross section. (~ GERANIUM)
    - 26b Grains smaller (SIZE), weakly triangular in cross section (~ POTENTILLA/DASIPHORA in part)
    - 27a Grains elliptic to weakly circular (~MORPHOTYPE B)
    - 27b Grains elliptic, much longer pole to pole than across equator.
    - 28a Grains with evident protrusions of the pore, colpi short, scarcely noticeable (~ APIACEAE)
- 23b. Apertures colpate
  - 30a Ornamentation psilate (~MORPHOTYPE C).
  - 30b Ornamentation otherwise
    - 31a Ornamentation homobrochate (~ MORPHOTYPE D)
    - 31b Ornamentation otherwise
      - 32a. Ornamentation bacculate, grains large, (~LINUM)
      - 32b. Ornamentation otherwise
        - 33a. Ornamentation of minor cross-corrugated grooves (fossulate) (~CORYDALIS)
        - 33b. Ornamentation of scarcely perceptible irregular features (scabrate) (~RANUNCULUS IN PART)

34a: Annula subtending the apertures – making grains appear more or less triangular; Pollen often with viscin threads (ONAGRACEAE)

34b: Apertures not annulate – grains appear more or less circular (~ERICACEAE)

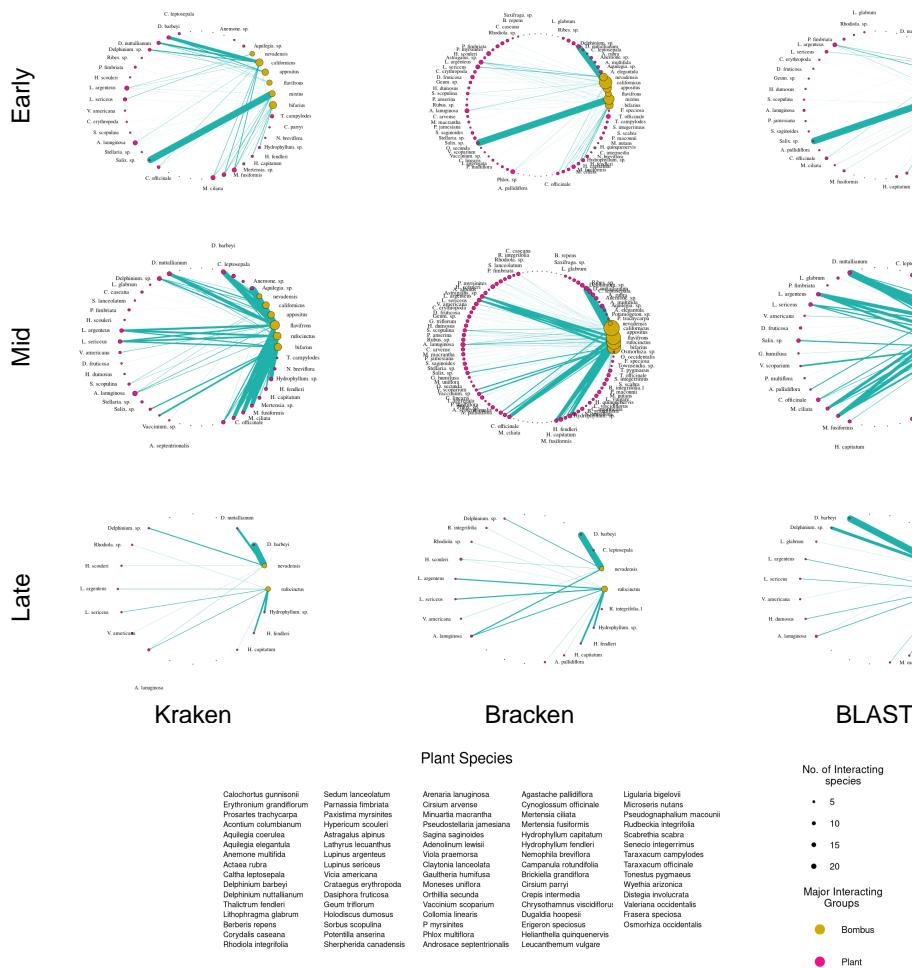

Morphotype A: Trifolium, Lupinus, Glycrrhiza, Mitella, Geum

Morphotype B: Lupinus, Lathyrus, Potentilla, Androsace, Bistorta, Vicia

Morphotype C: Jeffersonia, Micranthes, Prunus, Delphinium, Androsace, Penstemon, Orthocarpus, Scutellaria, Aquilegia, Castilleja, Draba)

Morphotype D: Salix, Boechera

### Comparision of Foraging Patterns from Three Sequence Alignment Algorithms

502 Appendix XX - Models used for Species Distribution Model Ensembles

503 *Generalised Linear Models (GLM)*

504 *Generalised Additive Models (GAM)*

505 The two machine learning models utilize Ensemble learning.

506 Decision trees, ...

507 Ensemble learning utilizes many sets of trees, each tree being composed of many binary decisions, to create  
508 a single model. Each independent variable (- or *feature*) may become a node on the tree - i.e. a location on  
509 the tree where a binary decision will move towards a predicted outcome. Each of the decision tree models  
510 which ensemble learning utilizes is a weak model, each of which may suffer due to high variance or bias, but  
511 which produce better outcomes than would be expected via chance. When ensembled these models generate  
512 a strong model, a model which should have more appropriately balanced variance and bias and predicts  
513 outcomes which are more strongly correlated with the expected values than the individual weak models.

514 *Random Forest (RF)* the training data are continually bootstrap re-sampled, in combination with random  
515 subsets of features, to create nodes which attempt to optimally predict a known outcome. A large number  
516 of trees are then aggregated, via the most common predictions, to generate a final classification prediction  
517 tree. Each individual prediction tree is generated independently of the others.

518 *Boosted Regression Tree (BRT)* (or Gradient Boosted tree) An initial tree is grown, and all other trees  
519 are derived sequentially from it, as each new tree is grown the errors in responses from the last tree are  
520 weighed more heavily so that the model focuses on selecting dependent variables which refine predictions.  
521 All response data and predictor variables are kept available to all trees.

522 Random Forest have high bias and low variance, where boosted regressions trees have low bias and high  
523 variances.

795 **List of Figures**

796    1	Phylogenetic tree of all biotically pollinated plant genera in the study area. The innermost	46
797    ring indicates every genus which Queen Bee's were observed to visit. The intermediate ring		
798    indicates that at least a single morphological pollen voucher slide was prepared for a member		
799    of the genus. The outermost ring indicates that sequence data were available for at least a		
800    member of that genus. Branch colors follow APG 4. . . . .		
801    2	Modelled dates of when major flowering events occurred . . . . .	47
802    3	Number of the ten most commonly visited plants which are also in the top ten most common	
803    sequences . . . . .	48	

## Biotically pollinated plant genera with morphological or molecular data

Figure 1: Phylogenetic tree of all biotically pollinated plant genera in the study area. The innermost ring indicates every genus which Queen Bee's were observed to visit. The intermediate ring indicates that at least a single morphological pollen voucher slide was prepared for a member of the genus. The outermost ring indicates that sequence data were available for at least a member of that genus. Branch colors follow APG 4.

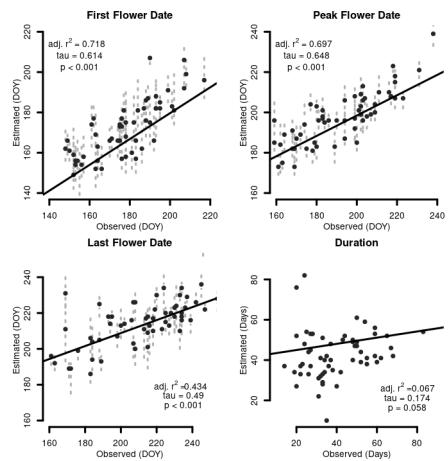

Figure 2: Modelled dates of when major flowering events occurred

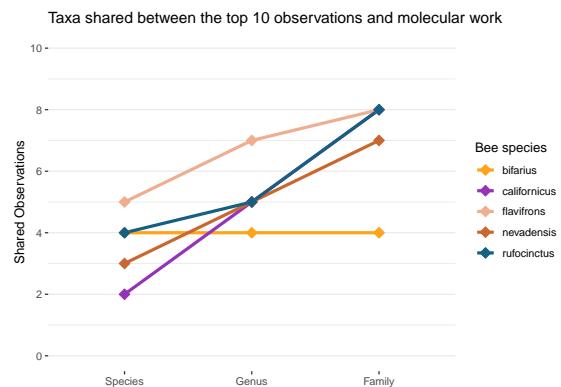

Figure 3: Number of the ten most commonly visited plants which are also in the top ten most common sequences
