⁴ **Abstract**

- 5 1) DNA Barcoding has been successful for the rapid analysis of ecological assemblages. Although
- 6 barcoding in the plant kingdom barcoding has been more difficult than others, and hence may begin
- 7 to lag behind other kingdoms.
- 8 2) Here we test the utilization of Angiosperms 353 probes to barcode plant species found in pollen
- 9 loads collected from Queen Bumble Bees.
- 10 3) To verify the accuracy for this barcoding system we compared the data to museum species, obser-
- 11 vation studies, and species distribution modelling to identify likely candidate species.
- 12 4) By utilizing Species distribution modelling we allow users to create a regionally appropriate sequence
- 13 databases which may use increase the alignment algorithms minimizing need for large computational
- 14 power, and run time.
- 15 5) We show that the Angiosperms 353 probes, which are currently being used in the largest ever plant
- 16 systematic endeavor, offers significant promise to metagenomic approaches.
- 17 6) Understanding plants in ecological contexts and understandings of their synecology.

¹⁸ 1 | INTRODUCTION

¹⁹ The inability to reliably identify plants to terminal taxon can limit our understanding of ecosystem function
²⁰ and interactions (Bortolus (2008)). This is especially true for genera where identification down to species
²¹ can be useful as specific bioindicators; defining ecological and behavioral properties (e.g. different species
²² of Sagebrush- *Artemisia* L., Willows - *Salix* L., and Sedges - *Carex* L.) (Gage & Cooper (2013)). In these
²³ instances the lack of species level data can hinder our understanding of the breadth of habitat which some
²⁴ species occupy, and their interactions with other species. This can be further complicated by the fact that the
²⁵ identification of organisms to terminal taxon is also often mired by lack of diagnostic characters(e.g. flowers,
²⁶ fruits, roots or combinations thereof), an increasing lack of taxonomic experts (Hebert *et al.* (2003)) and
²⁷ the presence of cryptic species (Janzen *et al.* (2017), Oliver *et al.* (2009)). Taxonomic verification can
²⁸ also be limited by the fact that revisiting field sites to identify material using morphological or chemical
²⁹ approaches, can be resource intensive and often does not work. The current methods to ameliorate this
³⁰ situation include: ignoring these ecologically relevant levels of detail, revisiting plots as diagnostic material
³¹ becomes temporally available, seeking the assistance from taxonomic specialists, or the use of barcoding
³² using molecular techniques (CITE)

³³ Recently molecular barcoding (the identification of a sample from a single organism *e.g.* a piece of leaf),
³⁴ or metabarcoding (the identification of a sample containing a mix of organisms *e.g.* soil), have shown
³⁵ considerable promise in many taxa (Ruppert *et al.* (2019)). For plants the success is a little more mix,
³⁶ with the identification of certain clades using barcoding being quite successful (Kress (2017)), however for
³⁷ many other clades the results have been more elusive (Liu *et al.* (2014), Group *et al.* (2011), Coissac *et al.*
³⁸ (2012)), while metabarcoding has incurred additional challenges for the currently available barcodes (Li *et*
³⁹ *al.* (2015), Kress & Erickson (2007), Group *et al.* (2009), Coissac *et al.* (2012)). Particular challenges for
⁴⁰ the utilization of the high copy number barcodes (*e.g.* ITS2, *rbcL*, *matK*, *trnH-psbA*) include their rates of
⁴¹ divergence, gene tree conflict, and hybridization (Coissac *et al.* (2016), Fazekas *et al.* (2009)).

⁴² Currently the largest plant systematic endeavor ever undertaken,by the Royal Botanic Gardens Kew, the
⁴³ Plant and Fungal Tree of Life (PAFTOL) is approaching completion (Baker *et al.* (2021a)). This data
⁴⁴ set will contain hybridization capture (Hyb-Seq) data from at least one species in each genus of the plant
⁴⁵ kingdom,14,000 represented species, using the popular Angiosperms353 (A353) probes, which includes 353
⁴⁶ single-copy orthologous loci, (Baker *et al.* (2021a), Johnson *et al.* (2019)). These publicly available data
⁴⁷ serve to provide a taxonomically comprehensive backbone for plant metabarcoding. The A353 probes are
⁴⁸ currently being used in many other plant phylogenetic studies increasing the sampling depth of many clades

49 (Baker *et al.* (2021b)). Data from the 10kP project, which seeks to develop reference genomes from a
50 phylogenetically diverse suite of plants will contribute many more species upon it's intended completion,
51 slated for 2030. Similar projects such as the 'Darwin Tree of Life' which will sequence all described taxa in
52 Britain and Ireland, seek to sequence high amounts of genomes in geographic regions will contribute data
53 sets applicable to enormous spatial domains (Cheng *et al.* (2018), Life Project Consortium *et al.* (2022),
54 Lewin *et al.* (2022)). These data will promote the ability to apply metabarcoding to resolve a diverse array
55 of questions relevant to theoretical and applied ecology (Kress (2017), Hollingsworth *et al.* (2016)). However,
56 the application of metabarcoding still face challenges relating to the enormity of the genomic data sets and
57 the computational power required to process sequence data.

58 Herein we have resolved major components of the problems of identifying plant material without diagnostic
59 morphological character states using the A353 Hyb-Seq probes (Johnson *et al.* (2019)), and custom species
60 sequence databases derived via species distribution modelling, and temporal filtering.

61 To increase the quality of metabarcoding results in plants, we are proposing reducing the number of possible
62 candidate species by generating a user specific databases relevant to the region of study and the ecological
63 characteristics of interest (Bell *et al.* (2022)). To achieve this goal, we first create a regional list of candidate
64 species using digital collections gleaned from herbaria, survey work, and citizen science (e.g. iNaturalist),
65 from a region exceeding the study area. For these candidate species, a modelling approach, such as logistic
66 regression, may be used to identify taxa which warrant further exploration e.g. determine their possibility of
67 presence in metabarcoding samples. We then use species distribution models to create potential distribution
68 maps for the candidate species to limit the impact of spatial and taxonomic biases in the species list and
69 account for spatial variations in niche availability throughout the study area. Species distribution models
70 (SDM's) examine the ecological conditions associated with known occurrence of a species to identify where
71 in the study area might suitable habitats. This approach has the benefit of greatly reducing the size of a
72 sequence database, which allows for the usage of genomic size data on personal computers. This approach
73 can significantly reduce processing time, particularly as as most next-generation sequence data is deposited
74 as raw-sequence reads.

75 As species interactions vary both in space and time (@~THOMSON1994 GEO?, CaraDonna *et al.* (2021)).
76 Contrasts in the flowering periods of many plant species, can provide an additional filter for identifying
77 material in certain types of metagenomic samples (Janzen (1967), Newstrom *et al.* (1994)). In high elevation
78 temperate regions, pollination interactions vary temporally and are characterized by high turnover in active
79 periods of species (CaraDonna *et al.* (2017)), however the overall shorter extent of the active growing
80 season in these systems results in the presence of few to any natural breaks, which reduces the utility of

81 these to operate as filters in the post-processing of sequence matches. Nonetheless, we work develop a
82 general approach which seems applicable to many areas which utilize the temporal dimension for classifying
83 sequences in metagenomic samples (but see Davis *et al.* (2022)).

84 We tested this metagenomic and informatics approach to determine to examine the foraging behaviour of
85 queen bumblebee, and compare this approach with direct observations and the pollen record, which has shown
86 some incongruity in several floral visitation networks involving smaller bodied fauna (Barker & Arceo-
87 Gomez (2021), Zhao *et al.* (2019), Alarcón (2010)). The assessment of the plant species compositions from
88 pollen is a desirable approach, with several potential applications, despite numerous potential complications
89 (Poronon *et al.* (2017), Bell *et al.* (2017), Sickel *et al.* (2015), Bell *et al.* (2019), Suchan *et al.* (2019),
90 Johnson *et al.* (2021)). The two foraging phases of the queen bumblebee life cycle are essential to 1) increase
91 their weight before diapause, and 2) increase their ovary weights while establishing their recently found
92 nests. Both of these time periods represent potential demographic bottlenecks in bumble bee populations
93 (Sarro *et al.* (2022), ...). Bumblebees are one of the only groups of insects with unequivocal quantitative
94 evidence for numerous population declines, while simultaneously serving as the most effective pollinators
95 in many temperate montane ecosystems (Cameron & Sadd (2020), Goulson *et al.* (2008), Williams (1982),
96 Colla *et al.* (2012), Bergman *et al.* (1996), Bingham & Orthner (1998), Grixti *et al.* (2009)). These
97 areas often represent the most diverse areas in the temperate and often offer the sole potential refugia for
98 multiple dimensions of biodiversity under climate change, whilst simultaneously experiencing the greatest
99 proportional changes in mean annual temperature (Brito-Morales *et al.* (2018), Pepin *et al.* (2022)). An
100 immediate understanding of how to manage previously overlooked keystone insect species, such as bumble
101 bees, is essential if the refugial potential of the temperate mountains are to be incorporated into their current
102 diversity (Loarie *et al.* (2009), Dobrowski & Parks (2016)).

103 2 | METHODS

104 2.1 Study System & Field Work

105 Observations and bee sample collection was conducted at The Rocky Mountain Biological Laboratory
106 (RMBL; 38°57.5" N, 106°59.3" W (WGS 84), 2900 m.a.s.l.), Colorado, USA (APPENDIX 1 for site informa-
107 tion), characterized by high-montane/subalpine Parkland vegetation communities. Pollinator observations
108 of *Bombus* Latreille spp. (Apidae Latreille) were conducted from May 29th - July 23rd of 2015 in six study
109 sites. Observations of *Bombus* foraging took place for one hour at each field site in three 50m transects, each

transect was in a major vegetation type (dry, and wet meadows, and Aspen forest), where all flower abundances were estimated and placed into bins of abundance. Corbiculae loads were, non-lethally, collected once from all Queen individuals encountered.

2.2 | Floral Visitation

... does this need more info and warrant a section independent of the above?

2.3 | Pollen Morphological identification

2.3.1 | Pollen Reference Library

To develop a reference library of pollen grains which may be present in corbiculae loads, an image reference collection of fuchsin-jelly stained (Beattie (1971)) slides was assembled from slides previously prepared by the authors (n = 21), and other researchers (n = 38) (Brosi & Briggs (2013)). Using five years of observational data on *Bombus* Queen Bee foraging at these study sites (Ogilvie unpublished), as well as the Vascular Plant Checklist (Frase & Buck (2007)), an additional 62 voucher slides for species were prepared and imaged at 400x (Leica DMLB, Leica MC170 HD Camera, Leica Application Suite V. 4.13.0) from non accessioned herbarium collections to supplement the number of species and clades covered (Appendix 3).

We used Divisive Hierarchical Clustering techniques to determine which plant taxa were distinguishable via light microscopy, and to develop a dichotomous key to pollen morphotypes. Ten readily discernible categorical traits were collected from each specimen in the image collection. These traits were transformed using Gower distances, and clustered using Divisive Hierarchical clustering techniques (Maechler *et al.* (2022)). Using the cluster dendrogram, elbow plot, and heatmaps (Hennig (2020)), of these results morphological groups of pollen which could not be resolved via microscopy were delineated, and a dichotomous key was prepared (APPENDIX NO.). This key was then used to identify the pollen grains sampled from corbiculae loads to morphotypes in a consistent manner.

2.3.2 | Pollen Corbiculae Loads

To prepare the pollen slides from corbiculae, all corbiculae loads were broken apart and rolled using dissection needlepoints to increase heterogeneity of samples. *Cerca* 0.5mm² of pollen was placed onto a ~4mm² fuchsin jelly cube (Beattie (1971)) atop a graticulated microscope slide, with 20 transects and 20 rows (400 quadrants) (EMS, Hartfield, PA). The jelly was melted, with stirring, until pollen grains were homogeneously spread

137 across the microscope slide. Slides were sealed with Canada Balsam (Rublev Colours, Willits, CA) followed
138 by sealing with nail polish to prevent oxidation; all samples are noted in *APPENDIX 3*. To identify the pollen
139 present in corbiculae loads, light microscopy at 400x (Zeiss Axioscope A1) was used. In initial sampling in
140 three transects, each pollen grain was identified to morphotype and counted; an additional two transects
141 were scanned for morphotypes unique to that slide, if either transect contained an unique morphotype than
142 all grains in that transect were also identified and counted. Subsequent to the first round of sampling, non-
143 parametric species richness rarefaction curves (Oksanen *et al.* (2022)), and non-parametric species diversity
144 rarefaction curves were used to assess the completeness of sampling (Chao *et al.* (2014), Hsieh *et al.* (2020)).
145 Slides not approaching the asymptote of the rarefaction curve were then re-sampled, and analysed iteratively
146 for up to a total of seven transects *APPENDIX 2*.

147 2.4 | Molecular Barcoding

148 2.4.1 | Species reference list

149 **2.4.1.1 Spatial Analyses** We generate a short list of potential candidate species we downloaded from the
150 Botanical Information and Ecology Network ‘BIEN’ (Maitner (2022)) all records adjacent to the field sites
151 to develop an ecologically relevant list of vascular plant species, with expected biotic pollination, which may
152 be present at the study area. To reduce the list of species to include in the genomic sequence databases, we
153 then generated Species Distribution Models (SDMs) for these taxa to predict their distribution throughout
154 the study area.

155 In order to minimize the number of species for which SDM’s were to be generated, BIEN was queried at a
156 distance of up to 100km from our study area and all plant species records were downloaded. To account
157 for the stochasticity of botanical collecting and offset the number of records associated with the research
158 station, this data set was bootstrap re-sampled 250 times, with 90% of samples selected, to create a testing
159 data set. The median of the logistic regression assessing the probability of occurrence of a species record as
160 a function of distance from the study area was used as a threshold distance, under which, to include species
161 as candidates for distribution modelling.

162 **2.4.1.2 Distribution Modelling** We used all occurrence records from BIEN ($n = 23,919$) within a 50km
163 border of the Omernik level 3 ecoregion, which includes the study area (*No. 21 “Southern Rockies”*) to
164 construct the species distribution model (Omernik (1987)). These records were copied into two, initially
165 identical, sets, one for generating machine learning models (ML; Random Forest, and Boosted Regression

166 Tree's), and the other for Generalised Linear (GLM) and Generalized Additive Models (GAM) (Barbet-
167 Massin *et al.* (2012)). Ensembled predictions have been shown to outperform their constituent models, on
168 average, and to reduce the ecological signal to the analytical noise of individual runs (Araujo & New (2007)).
169 No single method of producing SDMs has been shown to universally outperform others when faced with
170 a large and diverse number of applications, in our case a great number of species with differing biologies
171 and ecologies (Elith* *et al.* (2006), Qiao *et al.* (2015)). In the spirit of these findings, multiple families of
172 models, which can be generated together as they have similar requirements regarding the number and ratios
173 of Presence to Absence records were ensembled together (Barbet-Massin *et al.* (2012)).

174 We then generated 4,029 absence points, locations where the focal taxon is anticipated missing, through a
175 random stratification of 19% of the land cover in the area and included them in (Land Management (2019)).
176 To achieve a larger absence data set, we generated 1,000 pseudo-absence records for each taxon by randomly
177 selecting coordinates located at least 10km away from an occurrence record. For ML models, these pseudo-
178 absences were reduced so that the ratio of presence to absence records were balanced (Barbet-Massin *et al.*
179 (2012)). To achieve this, we removed absence records inside of 10% of the mean sample value of any predictor
180 variable the presence records; the required number of absence records were then randomly sampled.

181 To predict the potential distribution of each species we used 26 environmental variables at 30m resolution,
182 six related to climate, five soil, four topographic, four related to cloud cover, with the remaining reflecting
183 assorted abiotic parameters (Wilson & Jetz (2016), Wang *et al.* (2016), Hengl *et al.* (2017), Robinson *et al.*
184 (2014)) (**APPENDIX 6**). **These publicly available data sets, were selected as they** For linear
185 regression models these predictors underwent both *vifstep* (theta = 10, max observations = 12,500) and
186 *vifcor* (theta = 0.7, max observations = 12,500) to detect highly correlated variables, and collinear features
187 were removed leaving 16 variables (Naimi *et al.* (2014)).

188 Modelling: Random Forest and Boosted Regression Trees, were sub sampled with 30% test and two replicates
189 each before weighted ensemble based on True Skill Statistics (tss) (Naimi & Araujo (2016)). Generalised
190 linear models (GLM) and Generalised additive models (GAM) with 30% sub sampling and three replicates
191 each were also ensembled using the tss (Naimi & Araujo (2016), @). TSS was chosen as the ensemble
192 criterion as it has been shown to work across a wide range of species occurrences prevalence (Allouche *et*
193 *al.* (2006)). The results of these models were extracted on a cell-by-cell basis to a polygon feature derived
194 from a minimum-spanning tree which encompasses the study sites, and species from either ensemble with
195 greater than 50% mean habitat suitability across all cells were considered present for further purposes (Prim
196 (1957)).

197 A total of 535 species were modelled using Generalized Linear Models and Generalized Additive Models and

198 534 species were modelled using Random Forest and Boosted Regression Trees. To evaluate the accuracy of
199 the species distribution models, additional presence records from GBIF ($n = 61,789$), and AIM ($n = 12,730$)
200 were used as test and training sets ($n = 74,519$) for logistic regression (Occdownload Gbif.Org (2021), Land
201 Management (2019)). Additional novel absence records were generated from the AIM data set to create a
202 data set where each species has balanced presence and absences. Eleven or more paired presence and absence
203 records were required for this testing, resulting in 334 species being included in the logistic regression (Mdn
204 = 110.0, $\bar{x} = 223.1$, max = 1568 record pairs used) with a 70% test split (Kuhn (2022)).

205 **2.4.2 | Temporal Analyses**

206 To estimate the duration of dates in which plant species were flowering weibull estimates of several pheno-
207 logical parameters all spatially modelled taxa were developed (Belitz *et al.* (2020), Pearse *et al.* (2017)).
208 Only BIEN records which occurred in the Omernik Level 4 Ecoregions within 15km of the study area ($n =$
209 5 Level 4 Ecoregions, or conditionally 6 ecoregions if enough records were not be found in the nearest 5),
210 and which were from herbarium records were included. To remove temporally irrelevant herbarium records,
211 i.e. material collected during times which flowering is impossible at the study area due to snow cover, we
212 used the SnowUS data set (Iler *et al.* (2021), Tran *et al.* (2019)) from 2000-2017 were analyzed for the first
213 three days of contiguous snow absence, and the first three days of contiguous snow cover in Fall. Herbarium
214 records after the 3rd quantile for melt, and the 1st quantile for snow cover of these metrics were removed.
215 Species with > 10 records had their weibull distributions generated for the date when 10% of individuals had
216 begun flowering, when 50% were flowering, and when 90% of individuals had flowered, we used the initiation
217 and cessation dates, respectively, as effective start and ends of flowering. These estimates were compared to
218 groundtruthed data from a long term experiment 1974-2012, and the field data from 2015, using kendall's
219 tau.

220 **2.5.2 | Barcode references library**

221 All lab work was carried out at The Daniel F. and Ada L. Rice Plant Conservation Science Center at the
222 Chicago Botanic Garden, Glencoe, Illinois, U.S.A.

223 **2.5.2.1 | Sampling Species for Barcoding** Using five years (2015-2020) of observational data on *Bombus*
224 Queen Bee foraging at these studies sites, we identified the plant taxa most frequently visited by Queens
225 across all years. We sequenced the 12 most commonly visited taxa twice using samples collected from one site
226 within the Gunnison Basin River Drainage and one individual collected from another more distal population.

227 In addition we included a congener - or a species from a closely related genus to serve as an outgroup for
228 all 12 taxa. In addition we sequenced another 15 taxa commonly visited by *Bombus* workers, based on the
229 abundances, and immediate access to plant tissue, in the aforementioned data set (*APPENDIX 4*). Plant
230 collections were identified typically using a combination, of dichotomous keys and primary literature as
231 required (Flora of North America Editorial Committee (1993+), Hitchcock & Cronquist (2018), Ackerfield
232 (2015), Lesica *et al.* (2012), Cronquist *et al.* (1977+), Allred & Ivey (2012), *Jepson flora project* (2020),
233 Mohlenbrock (2002)).

234 **2.5.2.2 | Plant Genomic DNA Extraction** Plant genomic DNA was isolated from ~ 1 cm² of leaf tissue
235 from silica-gel dried or herbarium material using a modified cetyltrimethylammonium (CTAB) protocol
236 (Doyle & Doyle (1987)) that included two chloroform washes. DNA was quantified using a Nanodrop 2000
237 (Thermo Fisher Scientific, Waltham, Massachusetts, USA) and Qubit fluorometer (Thermo Fisher Scientific).

238 **2.5.2.3 | Pollen Genomic DNA Extraction** Pollen genomic DNA was extracted from corbiculae using
239 a CTAB based protocol modified from Lahlamgiah et al. and Guertler et al. (2014, 2014). A SDS extraction
240 buffer (350µL , 100mM Tris-HCl, 50 mM EDTA, 50 mM NaCl, 10% SDS v/v., pH 7.5) was added followed by
241 vortexing to allow dissolution of corbiculae. Pollen grains were then macerated with Kontes Pellet Pestles,
242 and the tip of these washed with 130 µL of the SDS extraction buffer, samples were then incubated for
243 1 hour at 30°C. This was followed by the addition of 10% CTAB solution (450ul, of 20 mM Tris-Cl pH.
244 8.0, 1.4 M NaCl, 10 mM EDTA pH 7.5, 10% CTAB, 5% PVP, ~85% Deionized water) and RNAse (10
245 uL of 10 mg/mL) and samples were incubated for 40 minutes at 37°C, on heat block (Multi-Blok, Thermo
246 Fisher Scientific, Waltham Massachusetts) set to 40°C. After 20 minutes incubation, Proteinase K (15 µL of
247 20mg/ml) and DTT (12.5 µL of 1M in water) were added, and the samples were further incubated at 60°C
248 for 1 hour. Samples were then incubated overnight at 40°C. 500 µL of Phenol-Chloroform-Isoamyl alcohol
249 (25:24:1) were added, vortexed, and centrifuged at 10,000 rpm for 10 minutes and the aqueous phase was
250 pipetted to a 1.5 ml centrifuge tube.

251 To precipitate the DNA, chilled Isopropyl alcohol & 3 mM Sodium acetate (5:1) equivalent to $\frac{2}{3}$ of the
252 volume of sample were added, with 1 hour of chilling at -20°C, followed by 10 minutes of centrifuging at
253 13,000 rpm. The supernatant was pipetted to a new 1.5 ml centrifuge tube, and 70% EtOH (400 µL) were
254 added before chilling at -20°C for 20 minutes followed by centrifugation at 13,000 rpm for 10 minutes. Both
255 tubes were then washed with 75% EtOH (400 µL), inverted, centrifuged at 13,000 rpm for 4 minutes, and
256 the solution discarded, then washed with 95% EtOH (400 µL) , inverted, centrifuged at 13,000 rpm for 4

257 minutes, and the solution discarded. Pellets were dried at room temperature overnight before resuspension
258 in nuclease free H₂O. Extractions were assessed using a Nanodrop 2000 (Thermo Fisher Scientific) and Qubit
259 fluorometer (Thermo Fisher Scientific). DNA extracts were then cleaned using 2:1 v./v. Sera-Mag beads
260 (Cytiva, Little Chalfont, UK) to solute ratio following the manufacturer's protocol, eluted in 0.5x TE, and
261 the eluent allowed to reduce by half volume in ambient conditions. DNA was quantified using a Qubit
262 fluorometer.

263 **2.5.2.4 | Fragmentation, Library Preparation & Target Enrichment** Library preparation was
264 performed using the NEBNext Ultra II FS-DNA Library Prep Kit for Illumina (New England BioLabs,
265 Ipswich, Massachusetts, USA) using slightly modified manufacturers recommendation. Fragmentation was
266 performed at ½ volume of reagents and ¼ enzyme mix for 40 minutes at 37°C, with an input of 500 ng cleaned
267 DNA. Adapter Ligation and PCR enrichment were performed with ½ volumes, while cleanup of products
268 was performed using SPRI beads (Beckman Coulter, Indianapolis, Indiana, USA) and recommended volumes
269 of 80% v./v. ethanol washes. The exception was the herbarium specimens which were not fragmented and
270 only end repaired, with similar library preparation of all samples. Products were analysed on 4% agarose
271 gels, and a Qubit fluorometer. Libraries were pooled and enriched with the Angiosperms 353 probe kit V.4
272 (Arbor Biosciences myBaits Target Sequence Capture Kit) by following the manufacturer's protocol and
273 Brewer et al. 2019. Sequencing was performed using an Illumina mi-Seq with 150-bp end reads, (NUSeq
274 Core, Chicago, Illinois).

275 **2.6 | Computational Processes and Analyses.**

276 **2.6.1 | Reference Library Data Processing** Sequences were processed using Trimmomatic, which
277 removed sequence adapters, clipped the first 3 bp, discarding reads less than 36 bp, and removing reads
278 if their average PHRED score dropped beneath 20 over a window of 5 bp (Bolger & Giorgi (2014), Tange
279 (2021)). Contigs generated were mapped to a reference with HybPiper with using target files created by
280 M353 (Johnson *et al.* (2016), McLay *et al.* (2021)).

281 **2.6.2 | Sequence Identification** A custom Kraken2 database was created by downloading representative
282 species indicated as being present in the study area by the spatial analyses from the Sequence Read Archive
283 (SRA) NCBI (Wood *et al.* (2019)). These sequences were processed in the same manner as our novel
284 sequences. The Kraken2 database was built using default parameters. Kraken2 was run on sequences using
285 default parameters (*APPENDIX 5*). Following Kraken2, Bracken was used to classify sequences to terminal

286 taxa (Lu *et al.* (2017)). Results from both Kraken2 and Bracken, results were reclassified manually to
287 identify terminal taxa. For example, when only a single species of a genus was known in the study area, but
288 our database used a representative of another taxon in the genus, this species was coded as the result.

289 **2.6.3 | Identification of Sequence Matching Loci** A local NCBI database was built using the same
290 processed novel and downloaded sequences as the previous database (Camacho *et al.* (2009)).

291 **3 | RESULTS**

292 **3.1 | Floral Observations**

293 The six sites were surveyed once weekly from May 27-July 27 for a total of 52 hours. A total of 723 queen-
294 pollen foraging interactions were observed (range per bee species by week range = 1-18, $\bar{x} = 3.46$, Mdn =
295 2), with a range of total observed interactions per bee species across this time period (min = 1, $\bar{x} = 59.08$,
296 Mdn = 19, max = 184). Plants varied widely in the number of interactions which they partook in with each
297 species of bee (range per plant species by week min = 1 - 20, $\bar{x} = 3.51$, Mdn = 2), with a range of total
298 observed interactions per plant species over this time period (min = 1, $\bar{x} = 20.26$, Mdn = 4, max = 141).
299 The number of plant species which bees were observed interacting with varied more narrowly (range = 1 -
300 18, $\bar{x} = 8$, Mdn = 6), interactions were observed with a total of 36 plant species.

301 A total of 66 corbiculae loads were collected from Bees, 64 of them from Queens.

302 [Figure 1 about here.]

303 **3.1 | Spatial Analyses**

304 [Table 1 about here.]

305 [Table 2 about here.]

306 The median (25.009 km) of the logistic regression assessing the probability of occurrence of a species record as
307 a function of distance from the study area was used as a threshold distance to include species for distribution
308 modelling. A 2-sample test for equality of proportions with continuity correction (X-squared = 13.254, df
309 = 1, p-value = 0.000136, 95% CI 0.04-1.00) was used to test whether more of the records located in the

310 broad ecological sites present at the field station, between the distance of the median (25.009 km) to the
311 third quantile (ca 43.830 km) of the regression distance, were true presences at the field station. Including
312 these records would have resulted in modelling an additional 222 species distributions of which 30 are true
313 presences, these taxa were not modelled.

314 Across the entire spatial domain of modelling all ensembled models ($n = 968$) had an accuracy of 0.84 (95%
315 CI 0.8356 - 0.8443), kappa = 0.68, p-value < 0.001, sensitivity = 0.80, specificity = 0.87, AUC = 0.92.

316 In the area of the minimum-spanning tree encompassing the field sites, of the 554 vascular plants with biotic
317 pollination syndromes, the 493 ML ensembles accurately predicted the presence of 362 (65.3%), incorrectly
318 predicted the presence of 64 (11.6%), incorrectly predicted 34 true presences (6.1%) as being absent, and
319 correctly predicted the true absence of 33 (6.0%). The balanced accuracy of the ensembled models is 0.627
320 (Sensitivity = 0.340, Specificity 0.914). Of the 554 vascular plants with biotic pollination syndromes, the
321 475 LM ensembles accurately predicted the presence of 286 (51.6%), incorrectly predicted the presence of
322 41 (14.3%), incorrectly predicted 93 true presences (16.8%) as being absent, and correctly predicted the
323 true absence of 55 (9.9%). The balanced accuracy of the ensembled models is 0.664 (Sensitivity = 0.573,
324 Specificity 0.754). Of the 554 vascular plants with biotic pollination syndromes in the flora 13 (2.3%) were
325 in the Orchid family and 41 (7.4%) are non-natives, both of which are restricted from the database, and can
326 only reduce the number of true predicted presences by roughly 10%.

327 At the six study plots, of the 117 plant species identified to the species level across the spatial extents of all
328 plots and duration of queen bee activity, the ML ensembles predicted the presence of 105 (89.7%) of them,
329 and LM ensembles 102 (87.2%). Of the missing species two (1.7%) are Orchids, six (5.1%) are non-native,
330 and one (0.85%) is of contested taxonomic standing, all of which (7.65%) are restricted from the initial query
331 database.

332 3.2 | Microscopic Pollen identification

333 Using the fuchsin jelly preparation and light microscopic analyses of grains and scoring of 10 character states
334 resulted in the establishment of 28 morphotypes which grains could be classified into. **APPENDIX 7**. From
335 the 37 samples that were counted and based on rarefaction we **had over % of expected morphotypes**
336 **found** (morphotype richness, $\bar{x} = 4.5$, Mdn = 4, min = 1, max = 9), **all samples had expected mor-**
337 **phototype diversity reach the asymptote APPENDIX 8**. The number of counted pollen grains in each
338 sample range from (514 - 19924, $\bar{x} = 3319$, Mdn = 1891).

339 **SUMMARY REQUIRED - Number of species from number of families, and how many species**

340 are identified to species versus number only to genera

341 [Figure 2 about here.]

342 **3.3 | Metabarcoding Pollen Identification**

343 **3.3.1 | Spatial Analyses to identify candidate taxa**

344 The median (25.009 km) of the logistic regression assessing the probability of occurrence of a species record as
345 a function of distance from the study area was used as a threshold distance to include species for distribution
346 modelling. A 2-sample test for equality of proportions with continuity correction (χ^2 -squared = 13.254, df
347 = 1, p-value = 0.000136, 95% CI 0.04-1.00) was used to test whether more of the records located in the
348 broad ecological sites present at the field station, between the distance of the median (25.009 km) to the
349 third quantile (ca 43.830 km) of the regression distance, were true presences at the field station. Including
350 these records would have resulted in modelling an additional 222 species distributions of which 30 are true
351 presences, these taxa were not modelled.

352 Across the entire spatial domain of modelling all ensembled models ($n = 968$) had an accuracy of 0.84 (95%
353 CI 0.8356 - 0.8443), kappa = 0.68, p-value < 0.001, sensitivity = 0.80, specificity = 0.87, AUC = 0.92.

354 In the area of the minimum-spanning tree encompassing the field sites, of the 554 vascular plants with biotic
355 pollination syndromes, the 493 ML ensembles accurately predicted the presence of 362 (65.3%), incorrectly
356 predicted the presence of 64 (11.6%), incorrectly predicted 34 true presences (6.1%) as being absent, and
357 correctly predicted the true absence of 33 (6.0%). The balanced accuracy of the ensembled models is 0.627
358 (Sensitivity = 0.340, Specificity 0.914). Of the 554 vascular plants with biotic pollination syndromes, the
359 475 LM ensembles accurately predicted the presence of 286 (51.6%), incorrectly predicted the presence of
360 41 (14.3%), incorrectly predicted 93 true presences (16.8%) as being absent, and correctly predicted the
361 true absence of 55 (9.9%). The balanced accuracy of the ensembled models is 0.664 (Sensitivity = 0.573,
362 Specificity 0.754). Of the 554 vascular plants with biotic pollination syndromes in the flora 13 (2.3%) were
363 in the Orchid family and 41 (7.4%) are non-natives, both of which are restricted from the database, and can
364 only reduce the number of true predicted presences by roughly 10%.

365 At the six study plots, of the 117 plant species identified to the species level across the spatial extents of all
366 plots and duration of queen bee activity, the ML ensembles predicted the presence of 105 (89.7%) of them,
367 and LM ensembles 102 (87.2%). Of the missing species two (1.7%) are Orchids, six (5.1%) are non-native,

368 and one (0.85%) is of contested taxonomic standing, all of which (7.65%) are restricted from the initial query
369 database.

370 **3.3.2 | Temporal Analysis**

371 The first date of modeled snow melt in the Gothic area ($n = 17$, $\bar{x} = 137.9$, Mdn = 135, 3rd quartile =
372 151), and the first date of a consistent winter snow base ($n = 17$, $\bar{x} = 299.9$, Mdn = 300, 1st quartile =
373 291) from 2000-2017, were used as delimiters for the inclusions of herbarium records in modelling. Of the
374 439 species predicted likely present in the area via logistic regression, 332 species (64.4%) with more than 10
375 records in the focal level 4 ecoregions ($\bar{x} = 35.016$, Mdn = 35, max = 96) had weibull estimates calculated,
376 an additional 56 species (11.2%) with enough contributing records from the “Sedimentary Mid-Elevation
377 Forests”, a large ecoregion generally just beneath the elevation bands occupied by the five ecoregions around
378 the study area had weibull estimates also calculated ($\bar{x} = 13.868$, Mdn = 13, max = 24).

379 Only 58 of these 388 species ($n = 34.6$, Mdn = 31) were able to be compared to plot based observational data
380 from the long term (1974–2012) data set (CaraDonna *et al.* (2014)). Of these species relatively high accord
381 was observed between the long-term ground truthed data set, and the modelled species. There was very
382 strong evidence that the weibull estimates were positively associated with the observed onset ($p < 0.0001$,
383 tau = 0.61), peak ($p < 0.0001$, tau = 0.65), and cessation of flowering ($p < 0.0001$, tau = 0.49). There was
384 moderate evidence that the weibull estimates had a weak positive association with the observed duration of
385 flowering ($p = 0.58$, tau = 0.17).

386 Of the previous 58 species compared, 47 of these could be compared to plot based data from the six sites
387 observed in 2015. Due to methodological differences, the peak flowering was not compared, and due to the
388 low performance of attempts to model ‘duration’ in the previous step it was also not compared. There was
389 very strong evidence that the weibull estimates were positively associated with the observed onset ($p <$
390 0.0001 , tau = 0.58), and cessation of flowering ($p < 0.0001$, tau = 0.40).

391 [Figure 3 about here.]

392 [Figure 4 about here.]

393 **3.3.1 | Molecular analysis of corbiculae loads**

394 The 54 corbiculae loads had DNA extracted and underwent various steps towards hyb-seq, in the end a total
395 of 44 corbiculae samples were sequenced, 7,752,353 reads were recovered from sequencing. The number of

396 reads per sequence varied widely (range = 76 - 508,795, $\bar{x} = 176,189.8$, Mdn = 138,395). Of the possible 353
397 loci, the number which were recovered from each sample, and informative to BLAST were range = 24 - 353,
398 $\bar{x} = 305.5$, Mdn = 331. The number of reads per loci from across all samples had a range of 178 - 506,653,
399 $\bar{x} = 20,688$, Mdn = 12,616. **APPENDIX X Reads Per Loci.**

400 After trimming 7,865,680 sequences remained. 10,682,538 reads were matched using Kraken, of the reads
401 classified by Kraken 10,160,768 reads were matched using Bracken, of the reads classified by Kraken 7,549,608
402 reads were matched using BLAST. Based upon subjective review of the three classifiers **APPENDIX X**
403 **MOLECULAR NETWORKS - 3 DIFFERENT ONES**, BLAST was chosen as the classification
404 method which yielded the most probable results by the field ecologist, and it's values were used for all
405 subsequent analyses.

406 [Table 3 about here.]

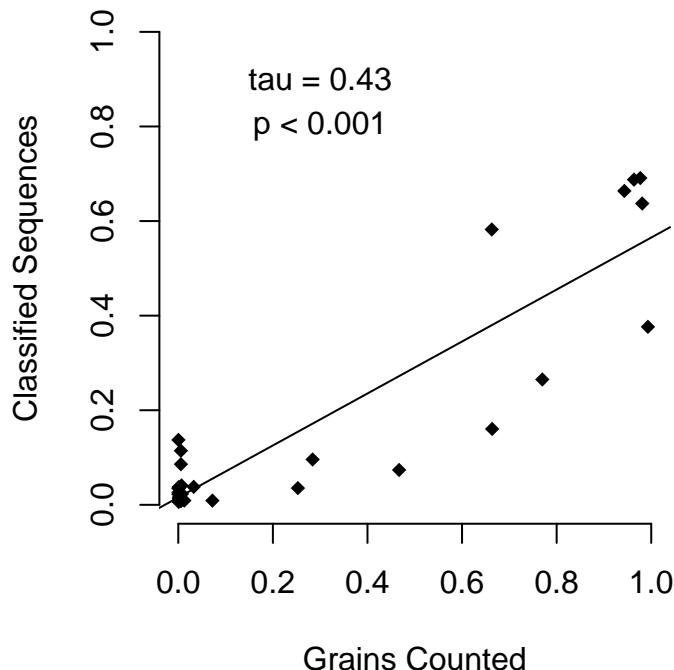

407 The initial classification of sequences which were made by BLAST were reviewed programmatically, using
408 predicted presence of the species (from spatial modelling), modelled flowering time (from temporal mod-
409 elling), and taxonomy (from existing sources). A sequential process was utilized which reassigned sequences
410 based on binary combinations of the factors above (Appendix XX). Given the relative sparsity of the number,
411 and relatedness, of species represented in the sequence database this was performed to: 1) Identify locally
412 present species represented by surrogates in the DB 2) Reduce false classifications of focal species 3) Identify
413 high confidence sequence matches. Of the top ten taxa which were identified by BLAST for the 680 distinct
414 records, 55.4% of the reads were classified to a species representing 48.3% of all classified reads, 41.9% of the
415 reads were classified to genus representing 48.3% of all classified reads, and 0% of the records were classified
416 to family.

417 Of the 0 classifications which were assigned to genera without any species predicted by spatial analyses, were
418 investigated by hand after post-processing steps. These were all assigned via post-processing conditions (: ,
419 APPENDIX XX). These were manually assigned to a variety of ranks, occasionally to genus - 0, and species
420 - 0, by consultation of the alpha-taxonomic literature (Sadeghian *et al.* (2015), Sennikov & Kurtto (2017),
421 Rabeler & Wagner (2016), Pusalkar & Singh (2015), Moore & Bohs (2003), Weber (1998)).

422 To determine at which level species in pollen loads could be detected the results of light microscopy were
423 compared to the molecular results. The pollen samples contained three morphotypes which could readily
424 be identified via microscopy. Two of these mapped to the clades (Boraginaceae & Heliantheae Alliance),
425 and one to a Asteraceae less Heliantheae. Boraginaceae grains were detected in 92.3% of samples where the
426 proportion of target grains were between 0.01-1 ($n = 13$ Mdn = 0.663). Asteraceae type 1, non-helianthoids,

427 were detected in 50% of samples where the proportion of target grains were between 0.001-0.01 ($n = 4$ Mdn
428 = 0.001) Asteraceae type 2, Helianthoids, were detected in 33.3% of samples where the proportion of target
429 grains were between 0.001-0.01 ($n = 6$ Mdn = 0.005); however, Asteraceae were detected in 80% of samples
430 where the proportion of target grains were between 0.001-0.01 ($n = 10$ Mdn = 0.003). Both morphotypes
431 of Asteraceae pollen were detected in 100% of samples where the proportion of target grains were between
432 0.01-1 ($n = 2$ Mdn = 0.338).

Correlation of Proportion Counted Grains and Sequence Reads

433 To detect whether the sequencing reads were semi-quantitative the subset of all pollen morphotypes distin-
434 guishable by microscopy were compared to the sequence reads. In all instances sequence reads were pooled
435 to the highest taxonomic rank associated with the morphotype, e.g. if both species of *Mertensia* Huth, or
436 one species and read only classified to genus were present in a sample, the reads were summed. The total
437 percentage of the ten most abundant grains per sample were then were then relativized to constitute the
438 entire sample.

440 The relationship between the number of pollen grains in a sample and the number of sequence reads is roughly
441 linear, where grains which are present in trace amounts are overestimated by sequence counts, while grains
442 present in high amounts are underestimated. This is likely due to the proportion of high false positives which
443 occur in the classification process with next-generation sequencing (Bell *et al.* (2021)). There was evidence
444 of a strong correlation between the proportion of grains per morphotype and the number of sequences per

445 group (0.43, $p < 0.0001$, $n = 32$).

446 To ascertain the extent to which records of multiple species in a family, which were suspected to be sampling
447 artefacts occurred in molecular samples an index of similarity, ala jaccard, the affinity index was used
448 to assess co-occurrence (Mainali *et al.* (2022), Mainali & Slud (2022)). Numerous taxa from the family
449 Ranunculaceae Jussieu (*Caltha* L. sp., *Thalictrum* L. spp., *Trollius* L. sp., *Aquilegia* L. spp.), had α scores
450 which indicated that they are only present when a more common confamilial taxa *Delphinium barbeyi* (Huth)
451 Huth *nuttallianum* Pritz. were recorded. A similar relationship was observed in the Hydrophyllaceae R.Br.
452 with samples placed in *Nemophila* Nutt., which only occurred when the more abundant *Hydrophyllum* L.
453 species were present. The size of flower of *Nemophila breviflora* A. Gray make it unlikely to be visited by
454 Bumble Bees, and it is a false positive. The floral morphology of *Thalictrum* spp. also makes it unlikely to
455 be visited (BELEIVE JANE SAID THIS- IF NOT STRIKE OUT), and while evidence of visits to Caltha
456 and *Trollius* are lacking, due to the association between the reads these results appear unlikely.

457 3.6 | Integrated Observational, Molecular, and Palynological Network

458 While the spatial results were used to declare the taxonomic composition of the sequence database, temporal
459 results were used in consideration with plant phylogeny to retroactively, reassign the assignment of sequences
460 to taxa. Essentially, if a sequence was identified to a taxon which was not known from the field site

461 For example a many sequences which mapped to the Asteraceae family, but which was flagged by temporal
462 filters and is present in both *B. nevadensis* Cresson and *B. rufocinctus* Cresson pollen is most likely *Frasera*
463 Walter, which failed extractions for the reference library failed (APPENDIX XX). A similar likely mismatch
464 could be between what was fide molecular evidence as *Agastache pallidiflora* (A. Heller) Rydb. but where
465 feeding was infrequently observed on *Pedicularis* L., likely due to this entire order being represented by only
466 a single molecular reference species.

467 Situations where SDM's led to incorrect results at the species level are evident with classification to *Scabrethia*
468 *Scabra* (Hooker) W.A. Weber, this match almost certainly representing *Wyethia arizonica* A. Gray (Weber
469 (1998)), a taxon known to be visited by Queen bee's via our floral observations. An expected inaccuracy of
470 the classification scheme is in genus level placements, e.g. were *Epilobium* L. (Onagraceae Juss.) spp. were
471 classified. However, given the small size of their flowers in the study area, these results more likely indicate
472 that a species of *Chamaenerion* Seg. (a segregate genus) such as *C. angustifolium* (L.) Scop. or *latifolium*
473 (L.) Sweet is occasionally utilized, as it supported by limited palynology data. An issue with reclassification
474 within the family level in combination with time included reclassifying *Parnassia palustris* L. to *Paxistima*

475 *myrsinites* (Pursh) Rafinesque. However, based on flower size it is more likely that the visited taxon was *P.*
476 *palustris*.

477 Regarding limitations of morphological data we suspect that there were two morphotypes of pollen identified
478 as Ericaceae Juss. were actually Onagraceae (Samples 19 & 44), based on molecular results.

479 It is not unlikely that much of the difference in the results between the observational and molecular work
480 are attributable to the challenges in detecting rare events in these smaller sizes. For example, no more than
481 10 bee corbiculae loads per species were sequenced with the Mdn = 5.5 . . . , and the median of interactions
482 with the top 5 plant sizes constituted 0.8283385 of the top interactions. Accordingly, combining the results
483 of floral observations, and palynology, molecular sequencing - both pre and post processing, we subjectively
484 developed re-classifications of the contents of pollen grains . . .

485 4 | DISCUSSION

486 We have demonstrated how the Angiosperms533 hyb-seq probes may be used for plant barcoding in a
487 metagenomic context (Johnson *et al.* (2019), Hollingsworth *et al.* (2016)). This was exemplified in an
488 ecologically relevant scenario, where the results have immediate implications for natural history guided
489 fundamental science and land management. The test pollen loads contained a number of closely related
490 taxa, some in notoriously morphologically difficult clades with rapid rates of diversification (e.g. *Mertensia*,
491 *Lupinus* L.), at naturally occurring proportions (Nevado *et al.* (2016), Nazaire & Hufford (2014)). We
492 incorporated spatial and temporal approaches for creating custom sequence databases an approach which
493 is readily applicable to any lab group with the capacity to perform next-generation sequencing across the
494 entirety of multiple continents, and which we expect to be highly beneficial in many study areas. By
495 combining insights from these novel approaches with an extensive observational field based study we show
496 how these methods may be applied to test a variety of hypotheses related to ecological interactions.

497 The SDM's which we generated, with relatively few occurrence records and few modelling iterations, per-
498 formed beyond expectations, likely due to the utility of the predictor variables and strong alignment of
499 vegetation by orographic precipitation in the study area. However, we had difficulties in evaluating our
500 predictions in an operational context. We utilized the database query approach, to only model species with
501 a high probability of not being dispersal limited to the focal area, and focused on a relevant subset of many
502 of these species ranges to reduce the contributions of range wide adaptions on habitat (Sork (2018), Joshi
503 *et al.* (2001)). While the models worked well compared to both test, and validation with external point
504 data, moving from points to polygon features was more difficult. We were able to compare our results to

505 1) a Flora, 2) lists of plants used by Bumble Bees at plots; the former inappropriate in that it contained
506 a great number of species which we sought to use modelling to reduce *e.g.* all strictly alpine species, and
507 the latter inappropriate in that it contained only species relevant to *Bombus* but had no official ‘absence’
508 data. Further given the size of the minimum spanning tree which we extracted points to, a formal floristic
509 inventory would still be a time intensive process. Accordingly, we expect the real results of our data lay
510 somewhere in between these two evaluations; with an excess of species predicted present (Dubuis *et al.*
511 (2011), Calabrese *et al.* (2014), Pinto-Ledezma & Cavender-Bares (2021)), but few enough that they lend
512 themselves to metabarcoding. We observe that our models seemed very capable of effectively identifying
513 alpine species and removing them in binomial contexts. Difficulties in temporal models related to variability
514 in drivers of flowering phenology. AND SMALL SAMPLE SIZE

515 These results show that the overall results between **Bumble Bee ecology** observational and barcoding are
516 largely congruent. But that . . . We analyzed pollen loads from all of the most common bumble bee species
517 in the area (Pyke (1982)) Future analyses of the long term data set . . .

518 Results from palynological analyses show that several species of bee show near perfect fidelity to the genus
519 *Mertensia* on a per visit basis . . . General results show high congruence between foraging and molecular
520 results, indicating that concerns regarding mismatch between observational networks need not persist with
521 *Bombus* studies . . .

522 Some foraging preferences of *Bombus*, both at this field site and across a great many localities globally
523 emerge from this work, which reiterates the needs for land managers to maintain relatively high amounts
524 of members of the Fabaceae, Boraginaceae, and Ranunculaceae, in Western North American montane land-
525 scapes (Goulson *et al.* (2005), Goulson (2010), Liang *et al.* (2021), Bontsutsnaja *et al.* (2021)). Numerous
526 historic, and some ongoing, land management practices reduce the ability of many landscapes to support
527 stable populations of *Bombus*. Historic livestock grazing was often associated with the targeted removal
528 of many species of plants which are known to have compounds toxic to cattle. In particular, the removal
529 of locoweeds (Fabaceae: *Astragalus* L. & *Oxytropis* DC.) and larkspurs (Ranunculaceae: *Delphinium*) were
530 common across public lands administered by the United States Forest Service (Ralphs & Ueckert (1988),
531 Aldous (1919), Ralphs *et al.* (2003)). Further actions, generally initiated by early settlers, involved the
532 channelization and incising of streams, culling of beavers, and leaving cattle concentrated on higher order
533 stream banks for significant periods of time, all processes which lower the water tables and reduced the ex-
534 tent of stream-associated [riverine] wetlands and the mesic meadows fringes which provide habitat for many
535 species of tall *Mertensia* (Boraginaceae, *e.g.* *M. ciliata* Torr. G. Don.) widely distributed across Western
536 North America, and to an extent *Delphinium barbeyi* and many species of native *Trifolium* L. (Dahl (1990),

537 Naiman *et al.* (1988), Belsky *et al.* (1999), Cooke & Reeves (1976)). Fire suppression further resulted in the
538 succession of many Aspen (*Populus tremuloides* Michx.) groves to Conifer stands, decreasing the mosaic of
539 age structured habitats in many landscapes, adversely effects habitat for tall *Mertensia* species and several
540 species of *Delphinium* (Brewen *et al.* (2021), Keane (2002)). Finally the effects of Nitrogen deposition, es-
541 pecially given the West's rapidly growing population still pose adverse effects on the abundance of a variety
542 of species of Fabaceae at Urban-Rural interfaces (see Stevens *et al.* (2018), Fenn *et al.* (2003)). Current
543 solutions to these issues, involve targeted burns, reintroduction of beavers and beaver habitat analogs, and
544 the possibility of re-seeding a variety of 'locoweeds' and 'larkspurs' in areas now seldom used, or only used
545 for early, grazing. The highly enthusiastic response of land managers, and homeowners, to plant *Asclepias*
546 L., using genetically appropriate materials, to improve Monarch Butterfly (*Danaus plexippus* L.) habitat
547 provides an effective framework for the latter (Oberhauser *et al.* (2015), Basey *et al.* (2015)).

548 We have concerns regarding the number of persons training to become and practice botany, and grave
549 concerns regarding the funding mechanisms for floristic and field based botanical research and for centralized
550 authorities to produce consensus opinions on alpha taxonomy (Prather *et al.* (2004b), Kramer & Havens
551 (2015), Prather *et al.* (2004a), Crisci *et al.* (2020), Manzano (2021), Stroud *et al.* (2022)). To reduce
552 the effects of a low population density of botanists on the maintenance of and production of Flora's and
553 to foster meta-genomics across landscapes without field stations we utilized Species Distribution Modelling
554 to generate predictive species lists. In this proof of concept example we performed several iterations of
555 modelling runs, and several approaches (i.e. the 'linear models', and the 'machine learning'), which took
556 notable amounts of compute power. We suspect the possible deleterious nature of this endeavor may be
557 reduced by: 1) more field surveying by crews will reduce the need to generate as many species 2) fewer runs
558 of models, 3) only running machine learning models which do not require an explicitly process to reduce
559 spatial autocorrelation. However, given the time required to perform all aspects of a study, even our amount
560 of computation was negligible. Further, we are very optimistic about the possibility for persons to perform
561 these tasks, as mentioned we utilized roughly only one quarter of the records which were digitally available
562 for presence, and we suspect others will have enough records to perform this process nearly anywhere else in
563 the temperate. In certain scenarios modelling of predicted species via more formally tailored S(tacked)-SDM
564 or J(oint)-SDM approaches may be beneficial (Wilkinson *et al.* (2021), Pinto-Ledezma & Cavender-Bares
565 (2021), Schmitt *et al.* (2017)).

566 Tandem to the lack of continued expertise required to generate and maintain species lists, is the expertise
567 required to continue tracking when major phenological events occur in many plant species at relatively fine
568 scales or under novel climates. Knowledge of these events is currently limited to general time periods of only

569 a handful of phenological events and groups of organisms (e.g. flowering initiation, or trees) (Prather *et al.*
570 (2004a), Li *et al.* (2016)). While many programs and initiatives exist to collect phenological information on
571 subsets of easily identifiable charismatic species to detect major trends in phenology, these capture only a
572 subset of the extent diversity (Betancourt *et al.* (2005), Havens *et al.* (2007)). In many instances it appears
573 that while landscapes respond similarly to environmental variables which predict phenological responses,
574 that individual species vary widely in their responses to similar environmental cues, or respond to different
575 cues (Augspurger & Zaya (2020), Xie *et al.* (2015), Xie *et al.* (2018), CaraDonna *et al.* (2014)). As can
576 be seen here, predictions of when a single, major phenological event occurs is already data limited. A more
577 promising approach for the tropics may lay in utilizing circular statistics (Park *et al.* (2022)).

578 The nearly complete Plant and Fungal Tree of Life (PAFTOL) will provide a comprehensive phylogenetic
579 backbone of the entire plant kingdom, and the inclusion of A353 probes with lineage specific probe sets is
580 common in producing massive genetic datasets (Baker *et al.* (2021b)). We predict that the A353 probes
581 which it is utilizing to work nearly immediately for DNA barcoding of whole plant material, and that more
582 elaborate validation studies in controlled metabarcoding settings, utilizing existing experimental designs,
583 will have favorable results (Bell *et al.* (2017), Bell *et al.* (2019), Bell *et al.* (2021), Lamb *et al.* (2019)). In
584 particular the harvesting of loci with more variation in certain lineages, and or with more variable flanking
585 regions, will prove promising for identifying closely related plant material (CITE). We suspect that conserved
586 reaches of genes resulted in the high amounts of reads in somewhat obscure species. Given that the A353 loci
587 are nuclear, single copy, and a variety are present the possibility of identifying target loci for quantitative
588 purposes is high, without continual PCR enrichment is possible; this would align with relatively high efficacy
589 of WGS (Lang *et al.* (2019), Peel *et al.* (2019), Bell *et al.* (2021)). Recent evidence indicates that the
590 potential for identifying nearly cryptic taxa and even infra-specific inference, of either whole plant material,
591 and perhaps in metagenomic context are possible (Ottenlips *et al.* (2021), Wenzell *et al.* (2021), Loke et
592 al. in prep, Slimp *et al.* (2021), Beck *et al.* (2021)). We further believe that in synthetic phylogenetic
593 trees - with incorporation of NGS backbones - will allow in automatic reassignment of reads as a function of
594 phylogenetic distance with measures of uncertainty (Hinchliff *et al.* (2015), Smith & Brown (2018), Baker
595 *et al.* (2021a)).

596 5 | CONCLUSION

597 We believe that the combination of spatial and temporal models, united and guided by localized natural
598 history knowledge, provides the essential components of a bayesian framework for approaching the coarse

599 elucidation of ecological interactions using DNA Barcoding. Herein we crudely utilized this thinking via
600 binary outcomes, should a species predicted be predicted present or not? Is it unequivocally flowering
601 or not? Myriad data show biological systems and ecological interactions have more variance than can be
602 reasonably discretely parsed. We expect that within a bayesian framework studies of pollinator behavior
603 may be enacted via this approach at a landscape level, e.g. the scale of an entire drainage basin such as the
604 Gunnison which is quickly becoming one of the worlds few model ecosystems. We hope that the promise of
605 A353 probes as tools for metabarcoding play a role in these endeavors.

606 **AUTHOR CONTRIBUTIONS:** R.C.B conducted botanical collections, conducted all molecular lab
607 work, lead all analyses, and writing. J.E.O conceived, designed, and conducted all ecological fieldwork,
608 assisted with analyses, and writing. E.J.W. prepared, imaged, and collected trait data on pollen reference
609 slides, and assisted with analysis of trait data and writing a dichotomous key. S.T. assisted with spatial
610 analyses and writing. P.J.C assisted with ecological analyses and writing. J.B.F. conceived, and designed all
611 lab work, analyses, and integration of approaches, assisted with writing, and secured funding for molecular
612 work.

613 **ACKNOWLEDGMENTS:** Nyree Zerega for assistance obtaining herbaria loans and accessioning our
614 collections at CHIC. Pat Herendeen for assistance with virtually all aspects of preparing pollen vouchers and
615 the identification process. Hilary Noble, Zoe Diaz-Martinez, Angela McDonnell, & Elena Loke for assistance
616 with genomic library preparation. Ian Breckheimer for sharing the SDM predictor variables. We thank
617 the curators at the following herbaria for supplying tissue: Ben Legler at Stillinger (ID), Charles (Rick)
618 Williams at Ray J. Davis (IDS), (B)Ernie Nelson at Rocky Mountain (RM); and the collectors: D. Knoke,
619 L. Brummer, J. Boyd, C. Davidson, I. Gilman, M. Kirkpatrick, S. McCauley, J. Smith, K. Taylor, & C.
620 Williams. David Giblin & Mare Nazaire for sharing relevant sections of an advanced draft of FNA V. 15.
621 The Bureau of Land Management is thanked as many plant specimens were collected by R.C.B as a partner
622 or contractor to the agency; Sarah Burnett and Lauren Price are thanked for sharing AIM data. Sanda and
623 New England Biotech are gratefully acknowledged for technical support and generously sharing samples.
624 T.C.H. Cole for sharing the Angiosperm Phylogeny 4 colour palette. The Program in Plant Biology and
625 Conservation is thanked for funding. The holdings of the following herbaria were essential for this project:
626 AK, ALTA, ASU, BABY, BC, BM, BMO, BOON, BRIT, CANB, CAS, CHSC, CM, CMN, CNS, COLO,

* All Localities are in the United States of America

† Accession refers to whole-plant vouchers, all specimens are deposited at CHIC.

‡ Type Refers to whether both a physical and digital copy exist; 'Image' denotes only digital

§ Date refers to the Date of preparation.

⁶⁵³ POLLEN CLUSTER RESULTS SHOULD BE HERE

- 1a: Pollen shed in clumps (tetrads/polyads); grains generally triangular, with an annulus subtending the porate apertures (go 34)
- 1b: Pollen generally dispersed as single units (monads); grains seldom if ever with annulus.
- 2a: Apertures porate, always lacking colpi
- 3a: grain outline from equatorial view circular
- 4a: Pores distributed along the equator.
- 5a: Pores > 5 (stephanoporate)
- 6a: Ornamentation homobrochate (~ *MENTZELIA*)
- 6b: Ornamentation otherwise (~ *POLYGALA*)
- 5b: Pores < 5 (*CURRENTLY OPEN*)
- 4b: Pores +/- distributed across grain (pantoporate)
- 7a: Ornamentation with striate ornamentation (~ *POLEMONIUM*)
- 7b: Ornamentation otherwise
- 8a: Ornamentation, slightly irregular - without regularly repeating features (scabrate) (~ *STELLARIA*)
- 8b: Ornamentation forming regularly repeating (reticulate) cells of varying shapes.
- 9a: spacing between the grid cells large (lophate), the walls of the cells with another set of projecting ornamentation (~ *OPUNTIA*)
- 9b: spacing between cells small, the wall of the cells without projecting features.
- 10a: Pores extending beyond the reticulate grids (~ *ARENARIA*)
- 10b: Pores extending beyond the reticulate grids (~ *PHLOX*)
- 3b: Outline from equatorial view otherwise (usually slightly triangular)
- 11a: Outline elliptic (*CURRENTLY EMPTY*)
- 11b: Outline not elliptic, grains often with acute, if rounded, angles along sides (e.g., triangular, polygonal) (*EMPTY*)
- 2b: Apertures with colpi, occasionally also with pores in addition (coporate)
- 12a: Grains with bristles tapering to points (echinate), and tri-colporate.
- 13a: Grains uniformly echinate, less the apertures. (Asteraceae 1)
- 13b: Grains with echinate bristles on ridges of lophae (Asteraceae 2)
- 12b: Grains without echinate ornamentation - this lead includes projections with ornamentation with round tips.
- 14a: Grains with either less than 3 apertures, or with two distinct ornamentation types (generally $\frac{1}{2}$ psilate, $\frac{1}{2}$ reticulate).
- 15a. Grains apparently lacking any apertures. (~ *IRIS*)
- 15b. Grains aperturate
- 16a. Ornamentation on one face of grain psilate, the other homobrochate (~ *ZIGADENUS + ANTICLEA*)
- 16b. Ornamentation psilate across both faces of grain (~*ERYTHONIUM*)
- 14b. Grains with either 3 or more apertures, or with an elongated spiral like aperture
- 17a. Grain with spiral like colpi
- 18a. Spiral with deep well-defined furrows (~ *ERYTHRANTHE GUTTATA*, syn. obsolete. *MIMULUS*)
- 18b. Spirals without well-defined grooves, ornamentation evidently perforate (~ *RANUNCULUS ALISMIFOLIUS*)
- 17b. Grains with colpi these not forming irregular spiral motifs.
- 19a. Grains elliptic, essentially perfectly cylindrical along longest axis, except for minor inundations along equatorial region. Apertures, of two types (heteroaperturate). (~ *BORAGINACEAE*)
- 19b Grains shaped similar or not, but never heteroaperturate.
- 20a. From a polar view, grains notably polygonal (hexagonal), also evident when seldom seen from a equatorial view. (~ *PHACELIA*/ maybe *Hydrophyllaceae*, *Hydrophyllum* not sampled)
- 20b. From a polar view, grains not with 6 convex apices

- 21a. Grains elliptic, with a short colporate aperture on each psilate face, the edges of each face and the apices with a distinct (homobrochate) textured ornamentation. (~ POLYGONUM)
- 21b. Grains otherwise, not featuring a mix of ornamentations independent of the apertures.
- 22a. Ornamentation perforate, the three colpi very short, their longest axis parallel to the equator rather than perpendicular. These colpi often times almost appearing to be slightly raised on an annulus like feature (~ LONICERA)
- 22b. Grains not as described in all aspects of the above.
- 23a. Apertures colporate
- 24a. Outline of grain in equatorial view circular, ornamentation smooth. (~MORPHOTYPE A).
- 24b. Grains otherwise
 - 25a Grains distinctly triangular from polar view (go 26)
 - 25b Grains elliptic (go 27)
 - 26a Grains very large, clearly strongly triangular in cross section. (~ GERANIUM)
 - 26b Grains smaller (SIZE), weakly triangular in cross section (~ POTENTILLA/DASIPHORA in part)
 - 27a Grains elliptic to weakly circular (~MORPHOTYPE B)
 - 27b Grains elliptic, much longer pole to pole than across equator.
 - 28a Grains with evident protrusions of the pore, colpi short, scarcely noticeable (~ APIACEAE)
- 23b. Apertures colpate
 - 30a Ornamentation psilate (~MORPHOTYPE C).
 - 30b Ornamentation otherwise
 - 31a Ornamentation homobrochate (~ MORPHOTYPE D)
 - 31b Ornamentation otherwise
 - 32a. Ornamentation bacculate, grains large, (~LINUM)
 - 32b. Ornamentation otherwise
 - 33a. Ornamentation of minor cross-corrugated grooves (fossulate) (~CORYDALIS)
 - 33b. Ornamentation of scarcely perceptible irregular features (scabrate) (~RANUNCULUS IN PART)

34a: Annula subtending the apertures – making grains appear more or less triangular; Pollen often with viscin threads (ONAGRACEAE)

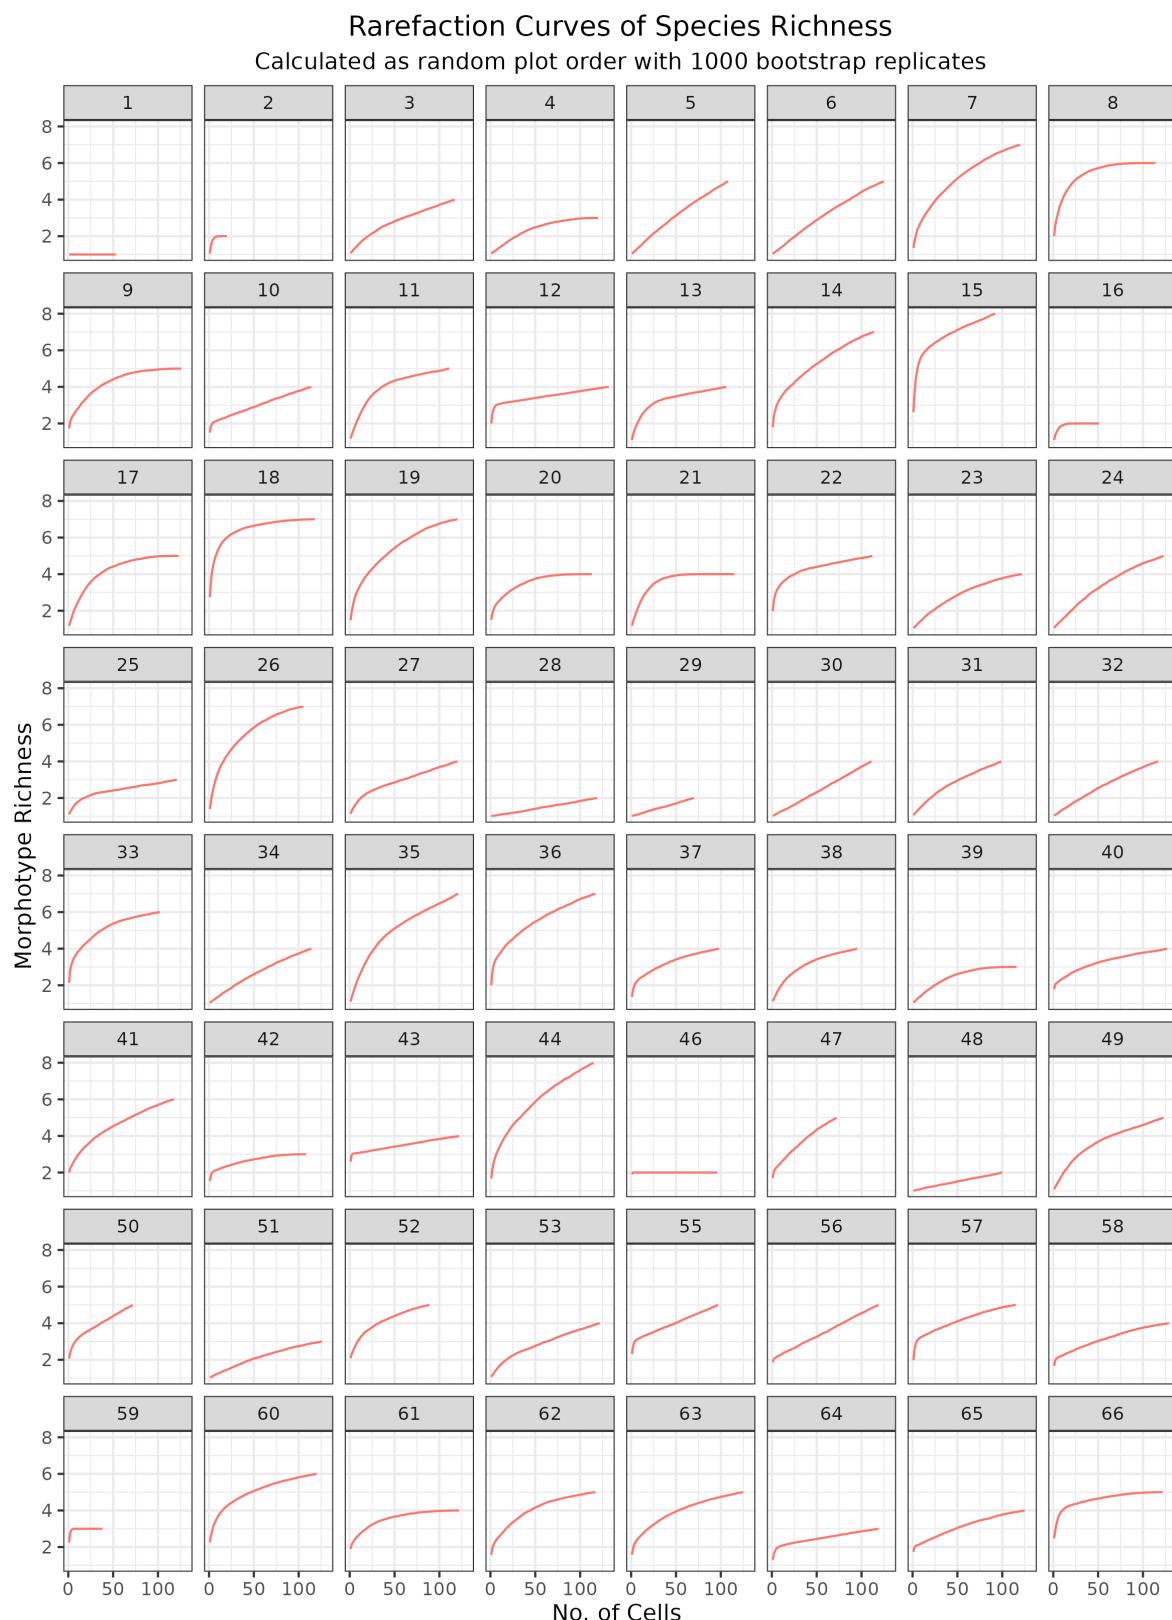

34b: Apertures not annulate – grains appear more or less circular (~ERICACEAE)

Morphotype A: Trifolium, Lupinus, Glycrrhiza, Mitella, Geum

Morphotype B: Lupinus, Lathyrus, Potentilla, Androsace, Bistorta, Vicia

Morphotype C: Jeffersonia, Micranthes, Prunus, Delphinium, Androsace, Penstemon, Orthocarpus, Scutellaria, Aquilegia, Castilleja, Draba)

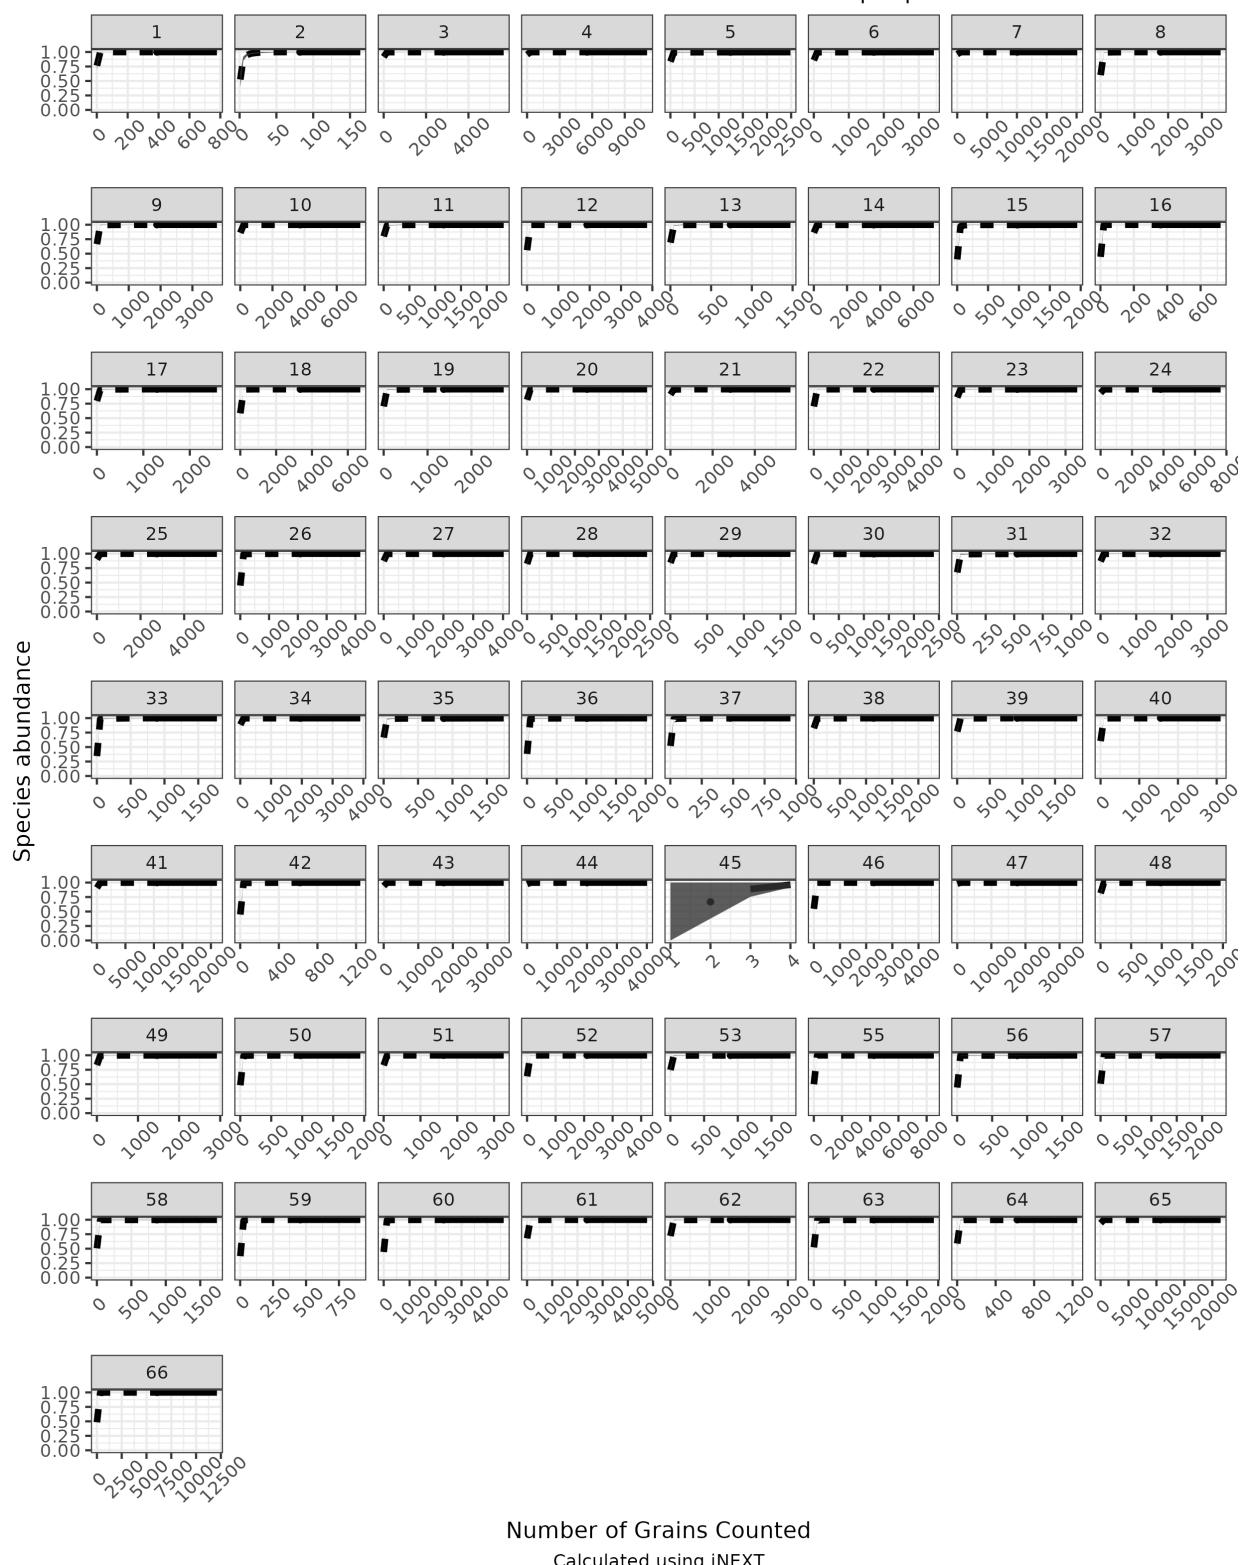

Morphotype D: Salix, Boechera

Used to assess completeness of subsampling. VEGAN package 'specaccum' function used

Comparision of Foraging Patterns from Three Sequence Alignment Algorithms

673 Appendix XX - Models used for Species Distribution Model Ensembles

674 The two machine learning models utilize Ensemble learning.

675 **Ensemble learning** utilizes many sets of trees, each tree being composed of many binary decisions, to
676 create a single model. Each independent variable (- or *feature*) may become a node on the tree - i.e. a
677 location on the tree where a binary decision will move towards a predicted outcome. Each of the decision
678 tree models which ensemble learning utilizes is a weak model, each of which may suffer due to high variance
679 or bias, but which produce better outcomes than would be expected via chance. When ensembled these
680 models generate a strong model, a model which should have more appropriately balanced variance and bias
681 and predicts outcomes which are more strongly correlated with the expected values than the individual weak
682 models.

683 **Random Forest (RF)** the training data are continually bootstrap re-sampled, in combination with random
684 subsets of features, to create nodes which attempt to optimally predict a known outcome. A large number
685 of trees are then aggregated, via the most common predictions, to generate a final classification prediction
686 tree. Each individual prediction tree is generated independently of the others.

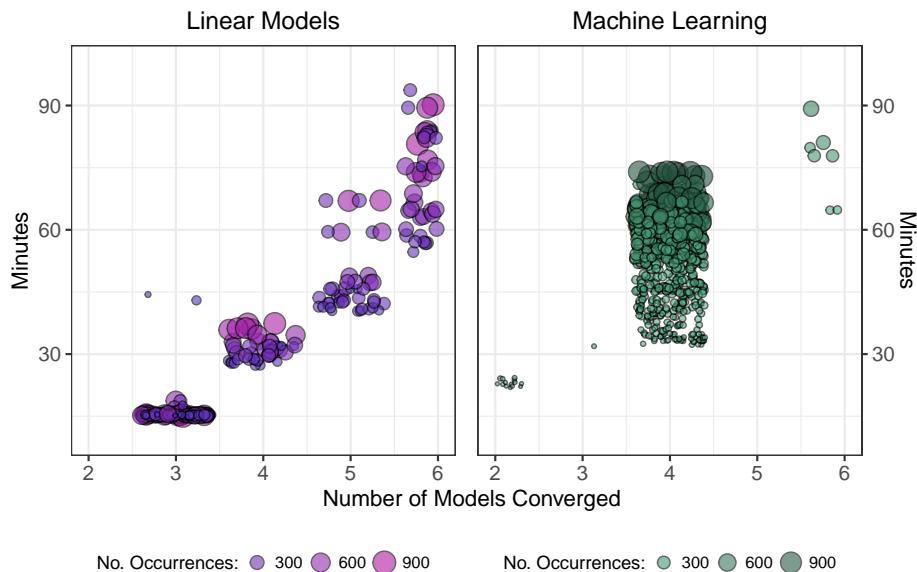

687 **Boosted Regression Tree (BRT)** (or Gradient Boosted tree) An initial tree is grown, and all other trees
688 are derived sequentially from it, as each new tree is grown the errors in responses from the last tree are
689 weighed more heavily so that the model focuses on selecting dependent variables which refine predictions.
690 All response data and predictor variables are kept available to all trees.

691 **Bias** predictions from an algorithm are systematically in error due to being prejudiced for or against certain
692 results, due to assumptions during learning.

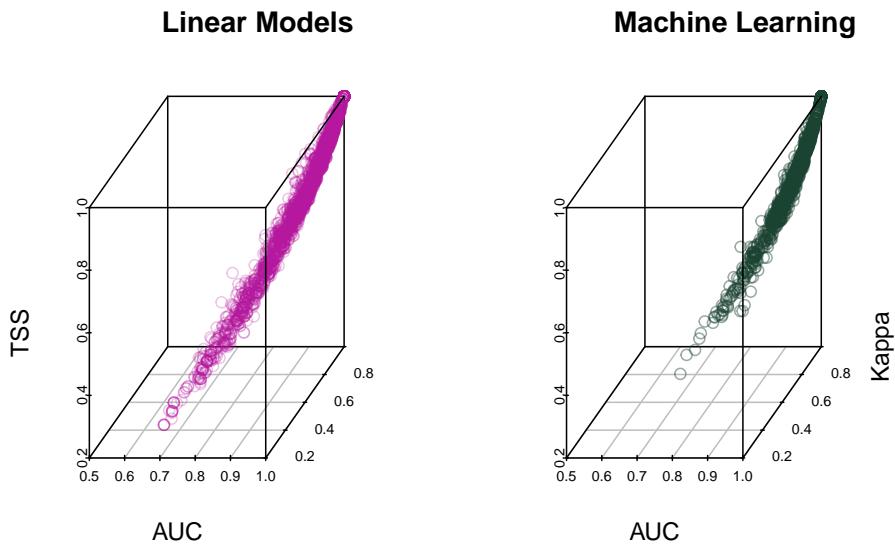

693 **Variance** errors in models due to an over-reliance and sensitivity of training to outliers in training data.

694 In general, Random Forest models have high bias and low variance, where boosted regressions trees have lower
695 bias and higher variance. Theoretically, the weaknesses and strengths of bootstrap aggregation (bagging) as
696 implemented by Random Forests are supplemented by the boosting.

Time Spent Fitting and Projecting Models onto Gridded Surfaces

Collectively it took 215 hours for all of the GLM and GAM to run, and for the converged models to be ensembled, and predicted onto a raster surface; it took 419 hours for the same process to be carried out for the Random Forest and Boosted Regression Tree models.

Results for each converged individual model which were then ensembled, using weights from the True Skill Statistic (TSS).

Table 1: Subset of Possible Combinations for re-classifying Sequences by Incorporating Ecological Factors

Spatial	Temporal	Congener	Confamilial	Congeners	Confamilials	Condition	Return	Rank
1	1	1	1	0	0	A.1	Input	Species
1	1	1	1	1	0	A.2	Input	Species
1	1	1	1	0	1	A.3	Input	Species
1	1	1	1	1	1	A.4	Input	Species
1	1	1	0	0	0	A.5	Input	Species
1	1	1	0	1	0	A.6	Input	Species
1	1	0	1	0	0	A.7	Input	Species
1	1	0	1	0	1	A.8	Input	Species
1	1	0	0	0	0	A.9	Input	Species
1	0	1	1	0	0	B.1	Congener	Species
1	0	1	1	0	1	B.2	Congener	Species
1	0	1	0	0	0	B.3	Congener	Species
1	0	1	1	1	0	C.1	Congener	Genus
1	0	1	1	1	1	C.2	Congener	Genus
1	0	1	0	1	0	C.3	Congener	Genus
1	0	0	1	0	0	D.1	Confamilial	Species
1	0	0	1	0	1	E.1	Confamilial	Family
1	0	0	0	0	0	F.1	Input	Species
0	0	1	1	0	0	G.1	Congener	Species
0	0	1	1	0	1	G.2	Congener	Species
0	0	1	0	0	0	G.3	Congener	Species
0	0	1	1	1	0	H.1	Congener	Genus
0	0	1	1	1	1	H.2	Congener	Genus
0	0	1	0	1	0	H.3	Congener	Genus
0	0	0	1	0	0	I.1	Confamilial	Species
0	0	0	1	0	1	J.1	Confamilial	Family

Note, for both ‘Congener’ and ‘Confamilial’ (*in the singular*) ‘1’ denotes that a species is present; in a sense the genus is monotypic in space and time. For both ‘Congeners’ and ‘Confamilials’ (*in the plural*), ‘1’ denotes that two or more species are present; ‘Confamilial’ again representing a monotypic entity in space and time.

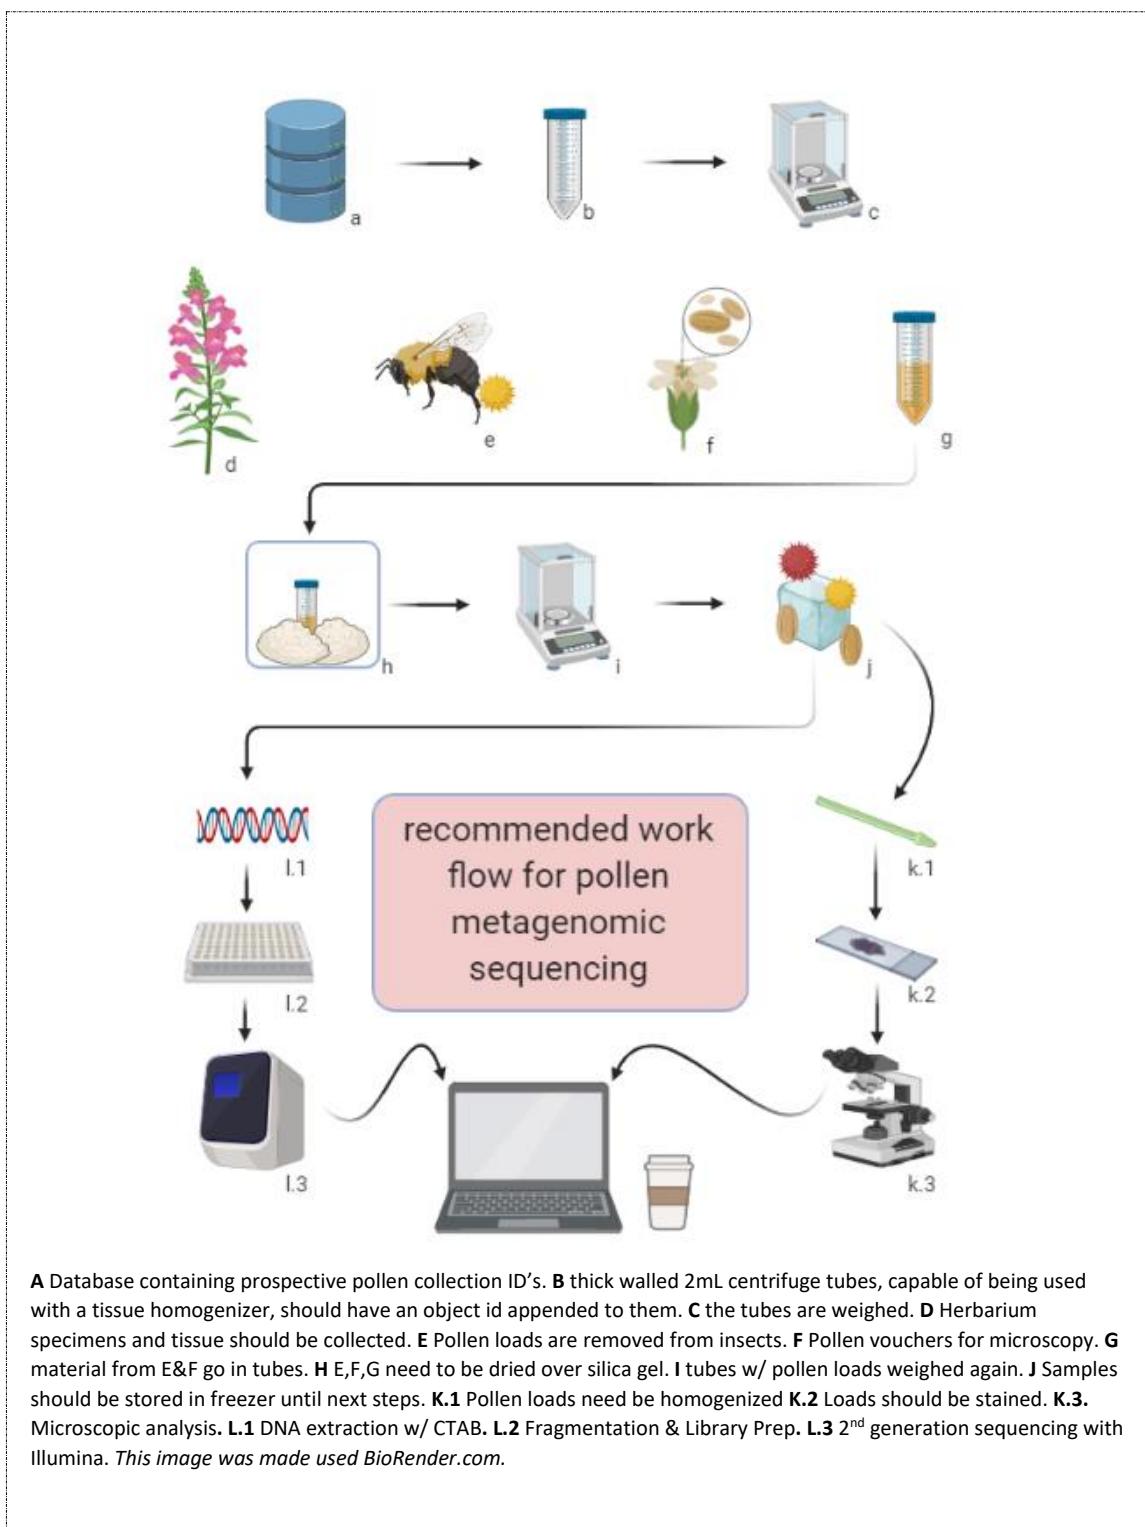

$$\begin{aligned} \text{Spatial} == 1 \& \text{ Temporal} == 1 \sim \mathbf{A} \\ \text{Spatial} == 1 \& \text{ Temporal} == 0 \& \text{ Congener} = 1 \sim \mathbf{B} \end{aligned}$$

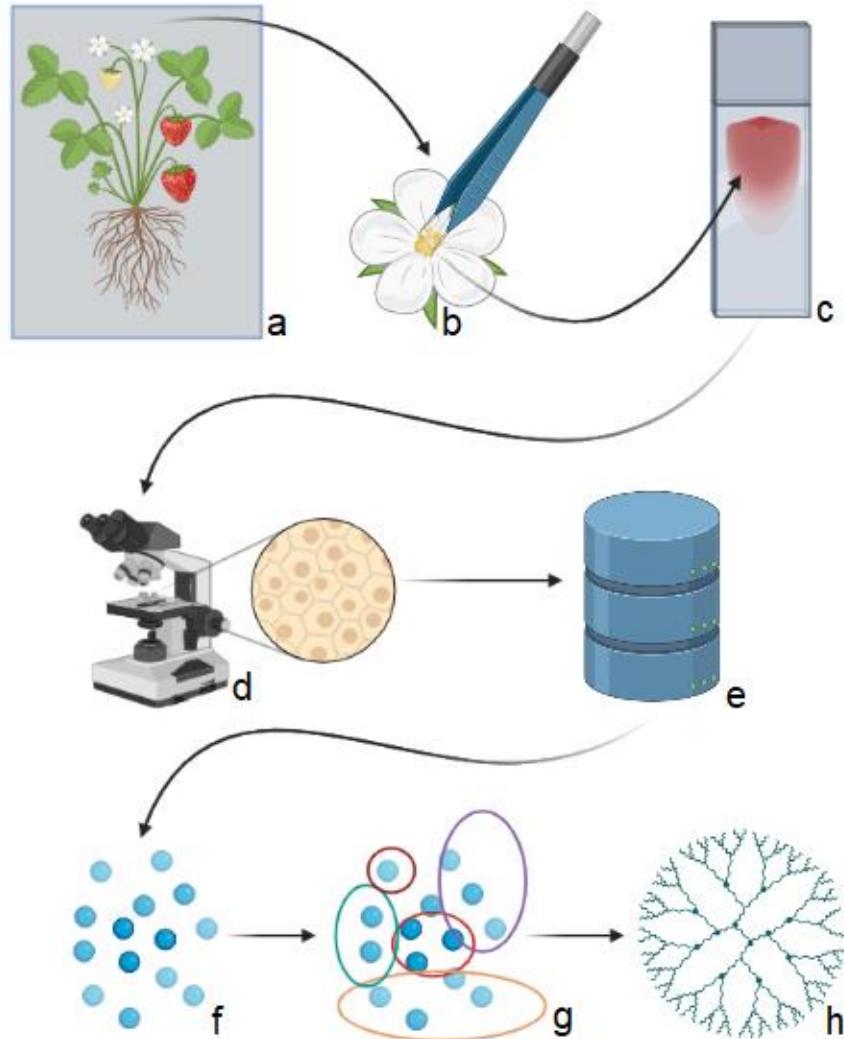

The temporal dimension is now buffered and a form of \mathbf{A} is employed
 $\text{Spatial} == 1 \& \text{ Temporal} +/- \text{ Buffer} == 1 \sim \mathbf{X}$

$$\begin{aligned} \text{Spatial} == 1 \& \text{ Temporal} == 0 \& \text{ Congeners} >= 2 \sim \mathbf{C} \\ \text{Spatial} == 1 \& \text{ Temporal} == 0 \& \text{ Congeners} == 0 \& \text{ Confamilial} == 1 \sim \mathbf{D} \\ \text{Spatial} == 1 \& \text{ Temporal} == 0 \& \text{ Congeners} == 0 \& \text{ Confamilial} >= 2 \sim \mathbf{E} \\ \text{Spatial} == 1 \& \text{ Temporal} == 0 \& \text{ Congener|s} == 0 \& \text{ Confamilial|s} == 0 \sim \mathbf{F} \end{aligned}$$

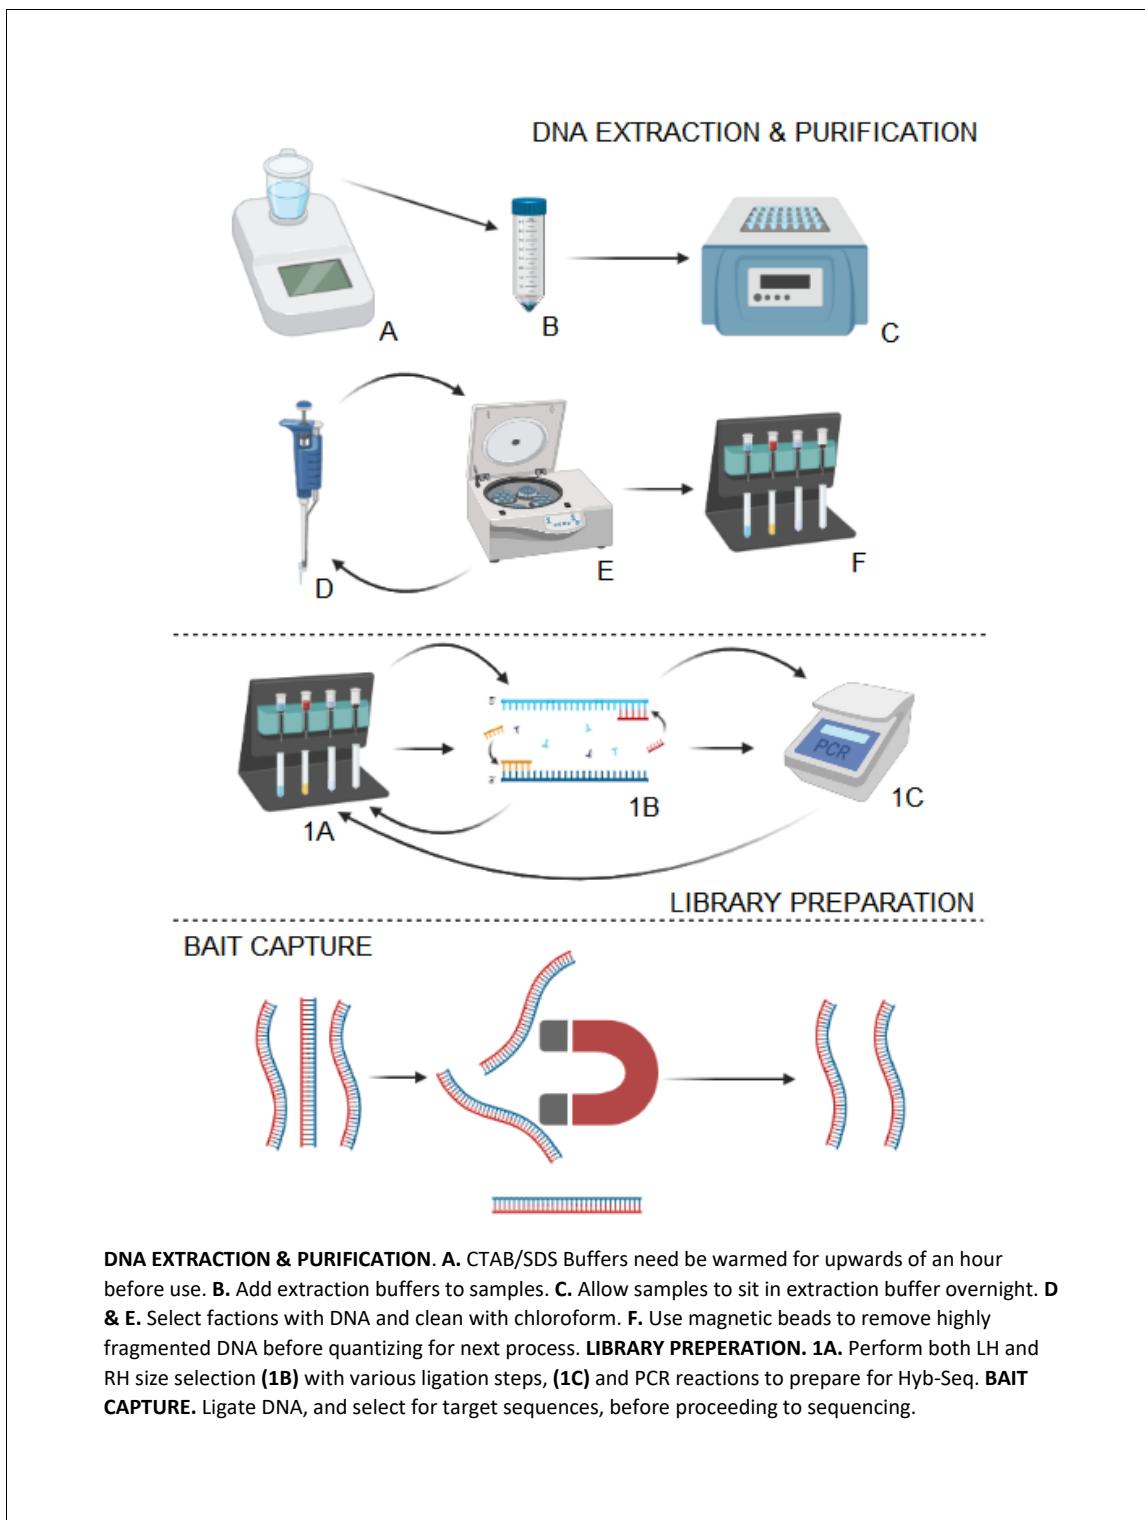

$$\begin{aligned} \text{Spatial} == 0 \& \text{ Temporal} == 0 \& \text{ Congener} == 1 \sim \mathbf{G} \\ \text{Spatial} == 0 \& \text{ Temporal} == 0 \& \text{ Congeners} == 1 \sim \mathbf{H} \\ \text{Spatial} == 0 \& \text{ Temporal} == 0 \& \text{ Confamilial} == 1 \sim \mathbf{I} \\ \text{Spatial} == 0 \& \text{ Temporal} == 0 \& \text{ Confamilials} == 1 \sim \mathbf{J} \end{aligned}$$

While the overall order matters, \mathbf{X} in particular may significantly alter conclusions.

A. An herbarium collection in flower from which pollen may be removed. **B.** The careful removal of pollen from dehiscent anthers using dissection tools. **C.** Place the pollen on a fuchsin jelly cube and melt it with stirring on a hotplate, for ca. 30 seconds. **D.** Microscopic imaging, of specimens and collection of character trait data. **E.** Immediate input and accessioning of files to a database. **F.** Ordination of traits into 2-dimensional space. **G.** Agglomerative clustering of data points into similar groups. **H.** Recovery of bifurcating decisions in development of clusters, or handwritten keys to visually diagnosable groups.

CTAB-DNA POLLEN EXTRACTIONS

Adapted from Lalhmangiahi et. al & Guertler et al. by Benkendorf, Fant, & Noble.

SAMPLE PREPARATION AND GRINDING

- a1) Add 380 μ L extraction buffer (100 mM Tris-HCl, 50 mM EDTA, 50 mM NaCl, 10% SDS, pH 7.5). This solution will need to be warm enough for the SDS to be in solution, requires heat and stirring.
- a2) Vortex samples at speed > 2000, until pellet breaks apart, ca. 20-30 seconds.
- a3) Use the Pellet Pestle Motor (Kontes) for ca. 15 seconds to macerate samples.
- a4) Add 100 μ L extraction buffer to wash the tip of the pestle into the centrifuge tube, and burst bubbles.
- a5) Allow to sit at 35°C for 1 hour, use vortex occasionally if sedimentation of pollen occurs.

EXTRACTION AND ISOLATION OF DNA

- b1) Warm CTAB buffer to remove any precipitants if present.
- b2) Add 480 μ L 10% CTAB buffer.
- b3) Add 10 μ L RNase (10mg/mL); invert by hand, incubate for 40 minutes at 37°C, increase heat to 60°C wait 20 minutes before continuing to b4.
- b4) Add 15 μ L proteinase K (20mg/mL) & 12.5 μ L DTT (1 molar in H₂O); invert by hand, incubate for 1 hr. at 60°C.
- b5) Incubate overnight at 40°C (*note: this is a hard stopping point*)
- b6) Add 500 μ L of Phenol-chloroform-isoamyl alcohol vortex samples, centrifuge at 10,000 rpm (10 min.)
- b7) Transfer the uppermost aqueous layer to a new 2 mL centrifuge tube.

DNA PRECIPITATION

- c1) Add slightly chilled Isopropyl alcohol & Sodium Acetate 3mM 5:1, equivalent to ca. 2/3 of the removed layer. Store at -20°C, 1 hour to allow precipitation.
(Note: potential stopping point for a day or more, samples can stay at -20°C for days)
- c2) Centrifuge at 13,000 rpm for 10 minutes.
- c3) Pour supernatant into new 2mL centrifuge tube, add 400 μ L 70% EtOH. Store at -20°C for 20 minutes.
- c4) Spin at 13,000 rpm for 10 minutes, discard supernatant.
for both tubes the following steps apply
- c3) Add 400 μ L of 75% EtOH, invert tube x3, centrifuge at 13,000 rpm for 4 minutes; discard supernatant
- c4) Add 400 μ L of 95% EtOH, invert tube x3, centrifuge at 13,000 rpm for 4 minutes, discard supernatant
- c5) Dry tubes in vacuum centrifuge for 30 minutes on medium heat at 15 mmHG.

RESUSPENSION OF DNA

- d1) Add 40 μ L of dna free H₂O to sample.
- d2) place on heat block at 37°C until pellet resuspends with occasional use of vortexes.

NOTES: a 10% CTAB preparation will not readily stay in solution, maintain it on heatblock until you are ready to use it. After adding it to extraction tubes move them to heat block immediately (*i.e.* in batches of 5-10).

Solutions

Extraction buffer (100 mM Tris-HCl, 50 mM EDTA, 50 mM NaCl, 10% SDS - pH 7.5, ca. 32 mL H₂O)

For 100 samples (50 mL solution)

10 grams SDS (Sodium Dodecyl Sulfate , d = 1.01 g/cm3)

146.1 mg Sodium Chloride (NaCl, mw = 58.4 g/mol)

930.6 mg EDTA (EthyleneDiamineTetraacetic Acid Disodium Salt dihydrate, mw = 372.24 g/mol)

Add 20 mL deH₂O

5 mL Tris-HCl pH 8.0 (1 molar- kept in fridge)

Fill to 50 mL with deH₂O

Auto clave on 'Liquid' setting for 15 minutes.

Dissolution may require heat and stirring (3 & 4 settings respectively, ca. 15 min.)

10% CTAB solution (20 mM Tris-Cl pH 8.0, 1.4 M NaCl, 10 mM EDTA pH 7.5, 10% CTAB, 5% PVP, 40 mL DiH₂O)

For 100 samples (50 mL solution)

add ~30 mL deH₂O,

1 ml Tris-HCl pH 8.0 (1 molar- kept in fridge; 2-Amino-2-(hydroxymethyl)propane-1,3-diol)

4.08 g Sodium Chloride (NaCl, mw = 58.4 g/mol)

4 mL EDTA pH 7.5 (0.125 molar – kept in fridge; 2,2',2'',2'''-(Ethane-1,2-diyl)dinitrilo)tetraacetic acid)

5 g CTAB (hexadecyl(trimethyl)ammonium bromide, mw = 364.45, FYI this is 274 mM)

Auto clave on 'Liquid' setting for 15 minutes.

2.5 g PVP-40 (1-ethenylpyrrolidin-2-one) – add after autoclave

Fill to 50 mL with deH₂O

Dissolution of PVP will require 2-3 hrs, at 65°C with stirring. Before use allow one hour of stirring and heat to resuspend all salts in the solution.

Sodium acetate solution (3mM)

For 100 samples (10 mL solution)

20.4 mg Sodium Acetate trihydrate (mw = 136.08 g/M)

to 50 mL deH₂O

Auto clave on 'Liquid' setting for 15 minutes.

Phenol-chloroform Isoamyl alcohol (25:24:1) Saturated with 10 mM Tris pH 8.0, EDTA

For 100 samples (50 mL solution) (no need to make, is bought)

25 mL Phenol

24 mL Chloroform (Trichloromethane)

1 mL Isoamyl alcohol
